FUTTYGURH, the military cantonment of Furruckabad, stands about three miles to the east of that city, on the opposite or left bank of the Ganges, being in lat. $27^{\circ} 22' N.$, and long. $79^{\circ} 41' E.$ Its name became peculiarly famous, or rather infamous, in the mutiny of 1857, less, however, for the outbreak that occurred on the spot, than for

the unparalleled sufferings of the hapless fugitives—men, women, and children.

FUTTYPUR, a town in the district of Saurashtra and Nerbudda, and sub-presidency of the North-west Provinces, stands on the Unjon, a tributary of the Nerbudda, about 20 miles from the point of junction, being in lat. 22° 33' N., and long. 78° 38' E. It is a place of some importance, as being the residence of three Gond rajahs.

FUTURE DEBT is a debt wherein the obligation to pay and the time for payment is fixed and certain, but the day for performance has not arrived. Of such a debt, it was said in the civil law *dece creditur ei nondum venit*; and it was distinguished from a contingent debt, i.e., a debt payable on the performance of a condition which was uncertain, in which it was said *dece creditur nec venit*. Thus, an obligation to pay six months hence is a future debt; an obligation to pay 'if my ship returns from Spain,' is contingent. In the event of the death or bankruptcy of a person having large commercial transactions, it is often of great importance that the right of the holders of such securities should be accurately fixed. In Rome, on the death or bankruptcy of a citizen, a creditor holding a claim for a future debt was entitled to payment, deducting a percentage proportionate to the date at which his debt was payable; but a contingent creditor only received a security for payment in case his debt should become payable. This general principle has been introduced into the legal systems of modern states. In Holland and in France, the rights of creditors having claims not immediately payable are based upon the rule of the civil law. In England, a future debt, in order to found a valid claim, must be in writing, but it may be constituted by bond, bill, or note or other security. By common law, such a claim could not be enforced until the actual time for payment has arrived; and formerly, in case of bankruptcy, a creditor on a debt of this kind was not allowed to insist in his claim. At the same time, the bankrupt's discharge was held not to release him from a debt which had not been admitted to claim in the process; and hence debtors were sometimes incarcerated for years on debts which they were wholly unable to discharge. See **IMPRISONMENT FOR DEBT**. This state of things was productive of manifest injustice on both debtor and creditor; on the latter, by excluding him from insisting in his claim at a time when he might have obtained a partial payment; on the former, by punishing him for his default when he was deprived of the means of making any return. The subject was frequently discussed in parliament before a remedy was applied. At last, by 6 Geo. IV. c. 16, s. 51, it was enacted that, in cases of bankruptcy, where a debt was not immediately payable, the creditor should be entitled to prove his debt, and

receive a dividend, deducting interest at 5 per cent. for the period which was to elapse before the date when the debt was payable in due course. By a. 56, debts payable on a contingency might be valued, and a dividend paid on the estimated value. Similar provisions were inserted in the 12 and 13 Vict. c. 196, ss. 172 and 177. By the last bankruptcy act, 24 and 25 Vict. c. 134, s. 153, it is enacted that a person having a claim for unliquidated damages, which are of the nature of a future debt, may have his claim assessed by a jury either in the court of equity, or before a common-law judge, or, in case of agreement between the parties, by the court without a jury.

By the common law of Scotland, the rule of the civil law, as to the rights of creditors having a future claim, has always been recognised. In the event of bankruptcy, creditors in both future and contingent debts are allowed to rank, but the latter only to the extent of receiving a security until the condition is purified. But by 19 and 20 Vict. c. 79, s. 53, which is now the ruling statute as to bankruptcy in Scotland, contingent creditors may have their debts valued, and may vote in the Sequestration (q. v.), and draw dividends proportionate to the valuation. It is also enacted, s. 14, that all creditors whose debts are not contingent may concur in the petition for bankruptcy. But the Scotch law affords to future debtors a further privilege, unknown to the system of the sister-country—viz., that of arrestment in security, whereby a creditor having a future claim is enabled, in case his debtor seem to be wilfully diminishing his means of discharging his debt, to attach the goods of the debtor as a security for the payment of his debt. See **ARRESTMENT**.

FYNE LOCH, an arm of the sea running north and north-east from the Sound of Bute, in the south of Argyshire, to beyond Inverary, in the north, and is bounded by the district of Cowal on the E., and by those of Argyre, Knapdale, and part of Caithness on the W. It is 43 miles long, 2 to 10 miles broad, and 40 to 70 fathoms deep. Its shores are deeply indented, and bordered by low bare hills, which rise higher and are wooded near Inverary. On the west side, it sends off a small branch leading to the Crinan Canal. Loch F. is celebrated for its herrings.

FYZABAD, a rapidly decaying city of Oude, stands on the right bank of the Ghogra, here a navigable river, in lat. 26° 47' N., and long. 82° 10' E. Originally an appendage, as it were, of Ayodha or Oude, the ancient capital from which the country took its name, F. became, in 1730, itself the seat of government. But in 1775, immediately after the annexation of part of Rohilkund (see **FURKHOUNG**), it was supplanted by Lucknow, which lay about 90 miles to the west, in the direction of the newly acquired territory.

G

THE seventh letter in the Roman alphabet, and in the modern alphabets derived from it. For the history of the character, see ALPHABET and letter C. The original and proper sound of G (corresponding to Gr. γ) is heard in *gun*, *gave*, *glad*. But the natural process which turned the *g* before *e* and *i* into that of *s* produced a similar change on G, so

that before *e* and *i* it came to be pronounced by the Latins like *dsA*. The sibilization of the letter *g* before *i* followed by a vowel, had begun as early as the 4th c. A.D., as is evident from the misspelling in inscriptions; in the case of *c*, the change can be detected much earlier. From the Latin, the *dsA*-sound of *g* passed into the Romanic tongues, and also into English. As a general rule in English, in words derived from the classical and Romanic languages, *g* has the hissing sound before *e*, *i*, and *y*, it has its natural sound in all words before *a*, *o*, and *u*; and it retains it in Teutonic words even before *e* and *i*.

G, in its proper power, belongs to the order of gutturals, *k* or *c*, *g*, *ch*, *gh*; of the two 'bare' gutturals, *g* is the final (or medial), and *k* the sharp, while *gh* and *ch* are the corresponding Aspirates (q.v.).

The following are some of the interchanges between *g* and other letters: Lat. *agor*, Gr. *agros*, Eng. *acre*, Ger. *acker*; Gr. *trigonon*, Lat. *trigonus*; Gr. *gonu*, Lat. *gonu*, Eng. *knee*, Lat. (g)nocco, Gr. *gignoco*, Eng. *know*; Lat. *genus*, Eng. *era*; Gr. *chm*, Ger. *ganz*, Eng. *goose* and *gander*; Lat. *hesternus*, Ger. *gestern*, Eng. *yester* (day); Lat. *germanus*, Span. *hermano*. The convertibility of *g* and *y* is seen in the old English participles in *y*, as *yelod*, corresponding to Sax. and Ger. *ge-*, in Ger. *gelb*, Eng. *yellow*, Ger. *tag*, Eng. *day*; Ger. *mag*, Eng. *may*, *yate* for *gate*; *yerd* for *garden*, Lat. *hortus*. In Italian, *gi* is substituted for *j*, as *Giulio* for *Julius*; and in French, which has no *w*, that letter is represented by *gu*, as *guerre*, *guarder*, for Eng. *war*, *ward* or *guard*. G has been frequently dropped out, as Lat. *noceo* for *gnocoo*, Eng. *enough*, compared with Ger. *genug*; *agone*, with *ge-gangen*; Lat. *magister*, Fr. *maître* or *matre*, Eng. *master*. *May*, Lat. *Maius*, contracted from *Magnus*, is from a root *mag*, or (Sansk.) *maā*, to grow: so that *May* is just the season of growth.

G, in Music, is the fifth sound of the natural diatonic scale of C, and the eighth sound of the chromatic scale. It stands in proportion to C as 2 to 3; is a perfect fifth above C, and the second harmonic arising from C as a fundamental note. In the solmization of Guido Aretinus, the note G was called Sol, Ra, or Ut, according as the hexachord began with C, F, or G. G major as a key has one sharp at its signature, viz., F sharp. G minor has two flats at its signature, viz., B flat and E flat.

GAAL, JOMUS, a Hungarian author, was born at

Nagy Karoly in 1811, studied at the college of Buda, and at the university of Pesth, and entered soon afterwards the administrative career, being attached to the Hungarian Council of Lieutenancy. G. began writing early, and proved equally successful when gossiping in the columns of Kossuth's famous *Pesti Hirlap*, and when engaged in translating a masterpiece of Cervantes, filling the periodicals with tales and novels, or furnishing original works for the National Theatre. The sketches of country-life as it was, and as it still continues on the vast plains of Hungary, are nowhere to be found more vividly and more truly exhibited than in G.'s comedies and tales. The following are some of G.'s original compositions: *Szirmay Ilona*, a novel in 2 vols. (Pesth, 1838); *Pestheri Notarius* (The Notary of Pesth, Pesth, 1838), a comedy in four acts—might be called the Hungarian comedy par excellence; *Szótörő*, a tragedy in five acts. Tales: *Pusztai Kaland* (An Adventure on the Hungarian Prairies); *Tengeri Kaland az Alföldön* (Seafaring Adventures in Lower Hungary); *Hortobágyi Éjszaka* (A Night on the Heath of Hortobágy). During the sojourn of the Hungarian Diet at Debrecen (1849), G. was editor of a journal combating extreme radical views.

GA'BRO, the name given by Italian geologists to a variety of greenstone composed of felspar and diallage. It is equivalent to euphotide or diallage rock.

GABELENTZ, HANS CONON VON DER, a distinguished German philologist, was born at Altenburg, 13th October 1807, and educated at the universities of Leipzig and Göttingen. In 1833, he published his *Elements de la Grammaire Mandchoue*, a new grammar, in which the entire idiomatic character of that language was developed in concise rules. He had, moreover, a share in the establishment of a journal devoted to Oriental sciences (*Zeitschrift für die Kunde des Morgenlandes*), and contributed to it some interesting papers on the Mongolian language. Along with J. Löbe, he also published a critical edition of the Gothic translation of the Bible by Ulfilas, with a Latin translation, and with a Gothic glossary and grammar appended (Leipzig, 1843—1846). G. was also the first philologist in Germany who undertook a scientific treatment of the dialects of the Finnish-Tartar stem. Besides a Syriac grammar (*Grundzüge der Syrischen Grammatik*, Altenburg, 1841), he furnished contributions to periodicals on the Mordvinian and Samoyed languages. He has since published some contributions to the science of language (*Beiträge zur Sprachkunde*). The first three parts were issued in 1852, and the first volume of a collection of his Philological Fragments (*Sprachwissenschaftliche Fragmente*) appeared in 1859, and a Dissertation on the Passive Voice (*Ueber das Passivum, Eine Sprachvergleichende Abhandlung*) in 1860.

GABELLE, a French word, derived from the German *Gabe*, gift or tribute, and originally used in

a general way to designate every kind of indirect tax, but more especially the tax upon salt. This impost, first established in 1286, in the reign of Philippe IV., was meant to be only temporary, but was declared perpetual by Charles V. It varied in the different provinces. Those that were most heavily taxed were called *paye de grande gabelle*, and those that were least heavily taxed, *paye de petite gabelle*. It was unpopular from the very first, and the attempt to collect it occasioned frequent disturbances. It was finally suppressed in 1789. The name *gabellous* is, however, still given by the common people in France to tax-gatherers.

GABION (Ital. *gabbia*, related to Lat. *cava*, hollow), a hollow cylinder of basket-work, employed in field or temporary fortification, and varying in size from a diameter of 20 inches to 6 feet, with a height of from 2 feet 9 inches to 6 feet. In constructing it, stout straight-stakes are placed upright in the ground in a circle of the required diameter, and are then wattled together with osiers or green twigs, as in the formation of baskets. The apparatus being raised, when completed, from the ground,

the ends are fastened, and the gabion is ready to be rolled to any place where it is desirable to form a breast-work against the enemy. Placed on end, and filled with earth, a single row of gabions is proof, except at the points of junction, against musketry fire, and by increasing the number of rows, any degree

Gabion.

of security can be obtained. The gabion has the advantage of being highly portable, from its shape, while with its aid a parapet can be formed with far less earth, and therefore in less time, than in cases when allowance has to be made for the slopes on both sides, which are necessarily present in ordinary earthen walls. The sap-roller consists of two concentric gabions, one 4 feet, the other 2 feet 8 inches in diameter, with the space between them wedged full of pickets of hard wood. In sapping (see *MINE*), these serve as substitutes for mantlets.

Stuffed gabions are gabions rammed full of broken branches and small wood; being light in weight, they are rolled before soldiers in the trenches, and afford some, though not a very efficient, protection against musketry fire.

Gabionnade is a line of gabions thrown up by troops as a defence, after being driven back from other more solid positions. In carrying a well-defended fortress, gabionnade after gabionnade has sometimes to be stormed before the besieged can be compelled to surrender.

GABLER, the triangular part of an exterior wall of a building between the top of the side walls and the slopes of the roof. The whole wall of which the gable forms the top is called a gable-end; party-walls, or the walls which separate two contiguous houses, and which belong equally to both houses, are called in Scotland 'mutual gables.'

The gable is one of the most common and characteristic features of Gothic architecture. The end walls of classic buildings had *Pediments* (q. v.), which followed the slope of the roofs, but these were always low in pitch. In mediæval architecture, gables of every angle are used with the utmost freedom, and when covered with the moulded and crocketed copes of the richer periods of the style, give great variety and beauty of outline.

Gabials, or small gables, are used in great profusion in the more decorative parts of Gothic architecture, such as canopies, pinnacles, &c., where

they are introduced in endless variety along with tracery, crockets, and other enrichments.

The towns of the middle ages had almost all the gables of the houses towards the streets, producing great diversity and picturesque effect, as may still be seen in many towns which have been little modernised. The towns of Belgium and Germany especially still retain this mediæval arrangement. In the later Gothic and the Renaissance periods, the simple outline of the gable became stepped and broken in the most fantastic manner. See *CORNIC STAIR*.

In Scottish law, a mutual gable or party wall, though partly built on the adjoining property, belongs to the builder, and he can prevent his neighbour from availing himself of it for the support of his house, until he has paid half the expense of building it. For the law of England on this subject, see *PARTY-WALL*.

GABOON RIVER, *Tua*, takes its rise in the Crystal Mountains, a chain in Western Africa, running almost directly east and west, parallel to, and about 80 or 100 miles distant from, the coast. Flowing first in the direction of north to south, it afterwards curves toward the north, and empties itself into the Atlantic in lat. about 0° 30' N., and long. 9° 10' E. Its mouth forms a bay of some 10 or 12 miles in length, with a breadth varying from 7 to 15 miles. The total length of the river is said to be about 120 miles. The G. is deep and sluggish, the mass of its waters being tidal, 60 miles from its mouth the tide rises to a height of from seven to nine feet. The climate is unhealthy; but the profits of the trade in ivory, which is obtained abundantly in the territories through which the river flows, induced a French colony to settle and build a fort at the mouth of the river in 1842 or 1843. In the same year, an American mission, which still continues in active operation, was established at Baraka, about eight miles up the river. The Gaboon country, besides ivory—of which, when the home demand is brisk, it yields about 80,000 pounds annually—produces ihar-wood, a dye-wood from which a dark-red dye is obtained, ebony, and copal of inferior quality. The banks of the river, from its source to the ocean, are occupied by about a dozen tribes, chief of which is the Mpongwa, who hold its mouth. This division of territory renders the ivory much more costly than it otherwise would be, the first owners in the interior not being allowed to take it direct to the white trader at the coast, but compelled to transmit it through the hands of the intervening tribes, each of whom makes a profit.

GABRIEL (Heb. the man or mighty one of God) is, in the Jewish angelology, one of the seven arch-angels. He appears in the book of Daniel as the interpreter of the prophet's vision (chap. viii.), and announces the future appearance of the Messiah (chap. ix. 21–27). In the New Testament, he reveals to Zacharias the birth of John the Baptist (Luke, i. 11), and to the Virgin Mary the birth of Christ (Luke, i. 26). According to the Rabbins, he is the angel of death for the people of Israel, whose souls are intrusted to his care. The Talmud describes him as the prince of fire, and as the spirit who presides over the thunder and the ripening of fruits. When Nebuchadnezzar besieged Jerusalem, G. is believed to have entered the Temple, by command of Jehovah, before the Assyrian soldiery, and burned it, thereby frustrating their impious intentions. G. has also the reputation among the Rabbins of being a most distinguished linguist, having taught Joseph the 70 languages spoken at Babel, and being, in addition, the only angel who could speak Chaldean and Syriac. The

Mohammedans hold G. in even greater reverence than the Jews, and regard him as the chief of the four most favoured angels who form the council of God, he is called the spirit of truth, and is believed to have dictated the Koran to Mohammed.

GACHARD, LOUIS PROSPER, principal archivist of Belgium, was born in France about the year 1800. He was originally a compositor; but having removed to Belgium, he took part in the revolution of 1830, and was naturalised in 1831. In the same year he was appointed to the useful and honourable post which he still retains (1862). G. has spent much time in examining the documents relating to Belgian history, which are to be found in the national archives and in those of Spain. His principal writings are, *Analectes Beligiques* (1830); *Documents Politiques et Diplomatiques sur la Révolution Belge de 1790* (1834); *Mémoires sur les Bollandistes et leurs Travaux depuis 1773 jusqu'en 1789* (1847); *Correspondance de Guillaume le Taciturne* (1847—1851); *Correspondance de Philippe II, sur les Affaires des Pays-Bas* (1848—1851); *Correspondance du Duc d'Albe sur l'Invasion du Comte Louis de Nassau en Frise* (1850); *Retraite et Mort de Charles-Quint* (1854), and *Relation des Troubles de Gand sous Charles-Quint* (1856). Prescott, the American historian, speaks highly of G., and of the importance of his labours in regard to the history and character of the Emperor Charles V. See Prescott's edition of Robertson's *History of Charles V.* (Boston, 1857). Recently (1859), G. published a series of historical documents bearing unfavourably upon the characters of Counts Egmont and Horn, which had the effect of stopping proceedings in regard to the erection of a national monument to these two noblemen.

GAD, the first-born of Zilpah, Leah's maid, was the seventh son of Jacob. His name is differently explained.—The tribe of Gad numbered in the wilderness of Sinai more than 40,000 fighting-men. Nomadic by nature, and possessing large herds of cattle, they preferred to remain on the east side of Jordan, and were reluctantly allowed to do so by Joshua, on condition of assisting their countrymen in the conquest and subjugation of Canaan. Their territory lay to the north of that of Reuben, and comprised the mountainous district known as Gilead, through which flowed the brook Jabbok, touching the Sea of Galilee at its northern extremity, and reaching as far east as Rabbath-Ammon. The men of Gad—if we may judge from the eleven warriors who joined David in his extremity—were a race of stalwart heroes; 'men of might, and men of war fit for the battle, that could handle shield and buckler, whose faces were like the faces of lions, and were as swift as the roes upon the mountains' (1 Chron. xii. 8). Jephthah the Gileadite, Barzillai, Elijah the Tishbite, and Gad 'the seer,' were also in all probability members of this tribe.

GADA'MES, or more accurately **GHADAMES** (the *Cydamus* of the Romans), the name of an oasis and town of Africa, the centre of divergent routes to Tunis, Tripoli, Ghat, and Tidikelt, is situated on the northern border of the Sahara, in lat. 30° 9' N., long. 9° 17' E., on the south-western boundary of the pashalic of Tripoli, and 310 miles south-west of the town of that name. It contains six mosques and seven schools; but the education offered to the young is limited to the reading of the Koran and a little Arabic writing. The gardens of G. grow dates, barley, wheat, millet, &c., and are watered by the hot spring (89° Fah.), from which the town had its origin. The climate is dry and healthy, though very hot in summer. The revenue of G., estimated at 10,000 mahboobs (£1700), is derived from annual tributes levied on property, and from

custom dues and tolls. It is an important entrepôt for manufactures and foreign goods from Tripoli to the interior, and for exports of ivory, bees-wax, hides, ostrich-feathers, gold, &c., from the interior to Tripoli. Previous to 1856, about 500 slaves, principally females, were annually imported at G.; but in that year a decree was issued by the sultan, peremptorily forbidding the traffic, which accordingly has been completely abolished. Pop. 4000, who are devoted Mohammedans.

GAD-FLY. See **BOT** and **TABANUS**.

GA'DIDÆ, an important family of malacopteron fishes, having a moderately elongated body covered with small soft scales, the head naked, the fins all soft and destitute of spines, the ventral fins placed under the throat and pointed, one dorsal fin or more, the air-bladder large. Some of the species are small, but others attain a large size. To this family belong the Cod, Ling, Hake, Dorse, Haddock, Whiting, Coal-fish, Burbot, &c. The species are widely distributed. Most of them are marine. A few, as the Burbot, are fresh-water fishes. The more important species are separately noticed.

GA'DWALL (*Anas strepera*, or *Chauliodus strepera*), a species of duck, not quite so large as the mallard, a rare visitant of Britain, but abundant in many parts of the continent of Europe, and equally so in Asia and in North America. It is also found in the north of Africa. Being a bird of passage, it is a native both of arctic and of tropical regions. The

Gadwall (*Anas strepera*).

G. breeds in marshes, and lays from seven to nine eggs. Except at the breeding season, it is usually seen in small flocks, and an individual is sometimes to be found in a flock of other ducks. Its voice is loud and harsh. It is much esteemed for the table, and is common in the London market, being imported chiefly from Holland.

GÆA, or **GE**, according to the Greek mythology, the goddess of the earth, appears in Hesiod as the first-born of Chaos, and the mother of Uranus, Pontus, and many other gods and titans. As the vapours which were supposed to produce divine inspiration rose from the earth, it was natural that G. should be regarded as an oracular divinity; and, in fact, the oracles at Delphi and Olympia were believed to have belonged to her in the earlier ages of their history. Her worship extended over all Greece, and she had temples or altars in most of the important cities. At Rome, G. was worshipped under the name of *Tellus*.

GAELIC LANGUAGE AND LITERATURE. The term Gaelic (Gwyddellican or Gadhelic) is used in two senses. In its wider signification, it designates

the northern branch of the Celtic languages, comprehending the Irish, the Highland-Scottish, and the Manx. See CELTIC NATIONS AND IRISH LANGUAGE AND LITERATURE. In its narrower signification, it designates the Highland-Scottish dialect, also known by the name of Erse or Irish. Mr W. F. Skene, one of the latest and best informed writers on the subject, holds that the differences between the language spoken by the Scotch Highlanders and the language spoken by the native Irish are (1) 'partly in the *pronunciation*, where the accentuation of the language is different, where that peculiar change in the initial consonant, produced by the influence of the previous word, and termed by the Irish grammarians *eclipsis*, is unknown except in the sibilant, where the vowel sounds are different, and there are even traces of a consonantal permutation; (2) partly in the *grammar*, where the Scottish Gaelic prefers the analytic form of the verb, and has no present tense, the old present being now used for the future, and the present formed by the auxiliary verb, where the plural of one class of the nouns is formed in a peculiar manner, resembling the Anglo-Saxon, and a different negative is used; (3) partly in the *idioms* of the language, where a greater preference is shewn to express the idea by the use of substantives, and the verb is anxiously avoided; and (4) in the *vocabulary*, which varies to a considerable extent, where words now obsolete in Irish are still living words, and others are used in a different sense.'—*The Dean of Lismore's Book*, introd. pp. xiv. xv. (Edin. 1862).

The origin of the differences thus described is a question still in dispute. Mr Skene contends that they are ancient, and enter into the organisation of the language. The Irish scholars, on the other hand, hold that they are comparatively modern and unimportant, and little more than provincial corruptions of the mother-language of Ireland. The late Mr Richard Garnett, one of the most learned of English philologists, is on the Irish side, holding 'that Irish is the parent tongue, that Scottish Gaelic is Irish stripped of a few inflections, and that Manx is merely Gaelic with a few peculiar words, and disguised by a corrupt system of orthography;' and, again, that the language of the Scottish Highlands 'does not differ in any essential point from that of the opposite coast of Leinster and Ulster, bearing, in fact, a closer resemblance than Low German does to High German, or Danish to Swedish.'—*Philological Essays*, pp. 202, 204 (Lond. 1859). That the north of Ireland, and the Scottish Highlands and West Islands, were, at an early period, peopled by the same race, or races, is admitted on both sides. Mr Skene further admits, that from about the middle of the 12th c. to about the middle of the 16th c., Ireland exercised a powerful literary influence on the Scottish Highlands; that the Irish sennachies and bards were heads of a school which included the West Highlands; that the Highland sennachies were either of Irish descent, or, if they were of native origin, resorted to bardic schools in Ireland for instruction in the language and the accomplishments of their art; that in this way the language and literature of the Scottish Highlands must have become, by degrees, more and more assimilated to the language and literature of Ireland; and that it may well be doubted whether, towards the middle of the 16th c., there existed in the Scottish Highlands the means of acquiring the art of writing the language except in Ireland, or the conception of a written and cultivated literature, which was not identified with the language and learning of that island. Mr Skene holds, at the same time, that a vernacular Gaelic, preserving many of the independent

features of a native language, existed among the Scottish Highlanders as a spoken dialect; and that a popular and unwritten literature existed in that native and idiomatic Gaelic, in the poetry handed down by tradition, or composed by native bards innocent of all extraneous education in the written language of Ireland.

The first books printed for the use of the Scottish Highlanders were a translation of Knox's Prayer Book in 1567, by John Carswell, Bishop of the Isles; a translation of Calvin's Catechism, in 1631; a translation of the Psalms of David, begun in 1659, and completed in 1694; and a translation of the Bible, published by the Rev. Robert Kirke, minister of Balquhider, in 1690. All these works are in the Irish orthography and Irish dialect; the last-mentioned work, indeed, is nothing more than a reprint of Bishop Bedell's Irish version of the Bible, with a short vocabulary of Scottish Gaelic words, to adapt it to the use of the Scottish Highlanders.

The first translations into the Scottish Gaelic were of Baxter's *Call to the Unconverted*, published in 1750; of the Psalms of David, in 1753, in 1787, and in 1807; of the New Testament, in 1767 and 1796; of Alleine's *Alarm*, in 1781; of the Old Testament, in 1783—1787, and in 1820; and of the Old and New Testaments, in 1826.

Vocabularies of the Scottish Gaelic were published in 1690, in 1702, in 1741, in 1795, and in 1815. The first Dictionary, by R. A. Armstrong, appeared in 1825; the largest and best was published under the auspices of the Highland Society of Scotland, in two quartos, in 1823. The best grammar is that of the Rev. Alexander Stewart, minister at Dingwall, published in 1801, and reprinted in 1812.

The oldest written poetry in the Scottish Gaelic is preserved in *The Dean of Lismore's Book*, written between 1511 and 1551, by Sir James Macgregor, vicar of Fortingall, and Dean of Lismore. It is now in the Advocates' Library at Edinburgh. Selections from it have been published at Edinburgh during the present year (1862), with translations by the Rev. Thomas M'Lauchlan, as well into English as into modern Scottish Gaelic, and with a preliminary dissertation by Mr W. F. Skene. The volume contains nine pieces ascribed to 'Ossian, the son of Finn,' who speaks of himself as contemporary with St Patrick, and pieces by later and less known writers, including a few of knightly or noble rank, such as Gerald Fitzgerald, fourth Earl of Desmond, in Ireland; Isabella Campbell, wife of the first Earl of Argyll; and 'Duncan MacCaillein, the Good Knight,' believed to be Sir Duncan Campbell of Glenorchy. The literary merit of the compositions is very slender.

The bibliography of the scanty literature of the Scottish Gaelic will be found in Reid's *Bibliotheca Scoto-Celtica* (Glasg. 1832). The modern names of most note are those of Robert Calder Mackay, or Robb Donn, as he is more commonly called in his native Sutherland, whose poems were published at Inverness in 1829; and Duncan Ban McIntyre, of Glenorchy, whose poems were published at Glasgow in 1834. The former was born in 1714, the latter in 1724; both were self-educated. The traditional prose literature has been collected and illustrated by Mr J. F. Campbell of Islay, in three pleasing volumes, *Popular Tales of the West Highlands* (Edin. 1860—1862).

Mr Skene has very clearly and fairly stated the long-disputed question as to the authenticity of the famous Poems of Ossian, published first in English, and afterwards in Gaelic, by Mr James Macpherson. The conclusions arrived at are: 1. That the characters introduced into Macpherson's poems were not invented by him, but were really the subjects

of tradition in the Highlands; and that poems certainly existed which might be called Ossianic, as relating to the persons and events of that mythic age. 2. That such poems, though usually either entire poems of no very great length, or fragments, had been handed down from an unknown period by oral recitation, and that there existed many persons in the Highlands who could repeat them. 3. That such poems had likewise been committed to writing, and were to be found to some extent in manuscripts. 4. That Macpherson had used many such poems in his work; but by joining separated pieces together, and by adding a connecting narrative of his own, had woven them into longer poems, and into the so-called epics.

The Scottish Gaelic speech is everywhere gradually, and in some places rapidly, losing ground; but it is still used, wholly or partially, in the public religious services of about 180 out of about 1000 congregations of the Church of Scotland.

GAETA (the Cajeta of the Latins), a strongly fortified maritime town of the Neapolitan province Terra di Lavoro, is picturesquely situated on an abrupt promontory projecting into the Mediterranean, and connected with the mainland by a low and narrow isthmus protected by solid walls. On the summit of the promontory stands the circular tower D'Orlando, said to be the ancient mausoleum of Lucius Munatius Plancus, the friend of Augustus. The beauty of the bay of G., which almost rivals that of Naples, has been celebrated by Homer, Virgil, and Horace. Cajeta, the ancient name of G. derives its origin, according to Virgil, from its being the burial-place of Cajeta, the nurse of Æneas. On the dismemberment of the Roman empire, G. became a centre of civilisation and commercial prosperity, and reached still further importance after the decadence of the eastern empire. In the growth of this early municipality is foreshadowed the commercial life and grandeur of the later Italian republics. Both in ancient and modern times, G. has sustained remarkable sieges, and recently it has been the theatre of several interesting events. In 1848, it became the refuge of Pope Pius IX., when the revolution at Rome compelled him to retire. In 1860, after the defeat of the Neapolitans on the Volturno by the forces of Garibaldi, G. was the last stronghold of the Bourbon dynasty of Naples, and surrendered after a protracted siege to General Cialdini. Many interesting classic remains have been found in G., including a fine marble vase by the Athenian sculptor Salpion. Its vicinity abounds in remains of Roman villas, &c. The citadel, which is of great strength, contains in its tower the tomb of the Constable Bourbon, killed at the taking of Rome in 1527. The inhabitants of G., who number about 15,000, derive their chief profits from the fisheries and their coasting-trade in oil, wine, and fruit—the chief productions of the surrounding country.

GÆTU'LIA, an ancient country of Africa, situated south of Mauritania and Numidia, and embracing the western part of the desert of Sahara. Its inhabitants belonged to the great aboriginal Berber family of North and North-western Africa; they were not in general black, though a portion of them dwelling in the extreme south, towards the Niger, had approximated to this colour through intermixture with the natives and climatic causes, and were called *Melanogastuli*, or 'Black Gætulians' (see Ptol. iv. 6, s. 16). The Gætulians were savage and warlike. They came into collision with the Romans for the first time during the Jugurthine war, when they served as light-horse in the army of the Numidian king. Cornelius Cosens Lentulus

led a force against them, and for his success obtained a triumph and the surname of Gætulicus (6 A. D.). The ancient Gætulians are believed to be represented in modern times by the Tuareks or Tawáreks.

GAFF, in a ship or boat, the spar to which the head of a fore-and-aft sail is bent, such sail having its foremost side made fast by rings to the mast, and its lower edge, in most instances, held straight by a boom. The thick end of the gaff is constructed with 'jaws' to pass half round the mast, the other half being enclosed by a rope; this serves to keep it close when the sail is hoisted or lowered. A gaff,

A, Gaff; B, Gaff-top-sail-yard; C, Boom; D, Sheet;
E, Gaff-top-sail.

with the sail called 'driver' or 'spanker,' and the gaff-top-sail, which is a small sail carried on the top-mast above the gaff, are shewn in the accompanying illustration.

GAFFLES, a name applied to the levers by means of which cross-bows were bent.

GAGE, THOMAS, an English general, who became governor of Montreal in 1760, and in 1763 succeeded general (afterwards Lord) Amherst as commander-in-chief of the British army in America. In 1774, when the difficulties between the colonies and Great Britain had already become very serious, General G. was appointed governor of Massachusetts. In peaceful times, his administration might in all probability have been popular and successful; but he was unequal to the exigencies of that trying period. It may indeed be doubted whether any one, whatever his abilities, could, while restricted to the rigorous policy of the home government, have succeeded in preserving the colony to the English crown. In April 1775, General G. sent an expedition to seize the military stores at Concord, and thus provoked the battle of Lexington, the first explosion of the American revolution. Soon after (May 5), the provincial congress resolved that 'no obedience was in future due to him [Gage], and that he ought to be guarded against as an unnatural and inveterate enemy.' According to Bancroft, 'Gage was neither fit to reconcile nor to subdue.' He was recalled, and sailed for England in the autumn of 1775. He died in 1787.

GAGE (Lat. *sodium* or *modium*) signifies a paw or pledge, and is derived, says Cowel, from the French *gager*. Hence, by changing *g* into *w*, we have *wage* and *wager*; as 'wager of law,' 'wager of battle,' wherein a person gave his pledge that he would sustain his affirmation; and, in the latter case, the glove was sent as a material pledge to

be redeemed by mortal combat. Hence also in England

Estate in Gage, which was of two kinds—*vivum vadium*, and *mortuum vadium*. See MORTGAGE. *Vivum vadium* was where an estate in lands was given in security of a debt, on condition that the estate should remain with the lender until he had made good the sum lent out of the profits of the land. So as in this case neither money nor land dieth or is lost, and therefore it is called *vivum vadium* (Co. Litt. 205 a). This mode of giving security has long gone out of use; yet there is no doubt that it was the original method in observance before the transaction assumed the form of a mortgage. It exactly corresponds with the Scotch form of a pure Wadset (q. v.).

GAGE, or GAUGE, an apparatus for measuring any special force or dimension; thus we have *pressure-gage*, *wind-gage* (see ANEMOMETER), *rain-gage* (q. v.), *wire-gage*, *button-gage*, &c. The simplest form of gage of dimension is the common *wire-gage*, by which the diameter of wire is measured. It is simply an oblong plate of steel, with notches of different widths cut upon the edge; these are numbered, and the size of the wire is determined by trying it in the different notches until the one is found which it exactly fits. The thickness of sheet-metal is tried by the same gage. There is a great want of uniformity in these gages—the Birmingham gage for iron-wire, sheet-iron, and steel differing from that used for brass, silver, gold, &c.; and these again from the Lancashire gages. It has been proposed, in order to obtain uniformity, and to enable definite descriptions and orders to be given with accuracy and certainty, that instead of the arbitrary numbers of varying signification now in use, decimal parts of an inch, tenths, hundredths, thousandths, or still smaller fractions, if necessary, be used, and that these be used for all diameters and thicknesses, such as wires, sheet-metals, buttons, watch-glasses, &c.; but such a scale has not yet come into general use. The gage commonly used for buttons, watch-glasses, and such like large diameters, is a rule with a groove cut lengthwise down the middle. Another metal rule, with a brass head, slides in this, and by means of a thumb-pin, may be pushed out at pleasure. The object to be measured is placed between *a* and *b* (fig. 1), and the width of this space is measured by graduations on the middle metal slide.

Fig. 1.

Fig. 2.

angle to each other, as *ab* and *cd* (fig. 2). Now, let us suppose the angle to be such that the distance between *a* and *c* is 2 inches, and that between *b* and *d* is 1 inch, while the lengths *ab* and *cd* are 10 inches. It is evident that for every inch of descent from *a* and *c* towards *b* and *d*, there will be a narrowing equal to $\frac{1}{10}$ of an inch; and for every tenth of an inch of such descent, there will be a narrowing of $\frac{1}{100}$ of an inch, and so on: thus we may, by graduating downwards from *ac* to *bd*, measure tenths by units, hundredths by tenths, and so on to still finer quantities if required. This is applicable to lengths as well as diameters. By means of fine screws with large graduated heads, Messrs Whitworth have measured small pieces of steel to the one-millionth of an inch (see MICRO-METER). Pressure-gages, wind-gages, &c. will be treated under the special subjects.—In railways, the gauge means the distance between the rails. See RAILWAY.

GAGERN, HEINRICH WILHELM AUGUST, FREIHERR VON, was born at Baireuth, 20th August 1799, and educated at the military school of Munich. On Napoleon's return from Elba, G. entered the army of Nassau, and served as lieutenant at Waterloo. After the peace, he devoted himself to the study of law at the universities of Heidelberg, Göttingen, Jena, and Geneva. On returning home in 1821, he entered political life under the government of Grand-ducal Hesse, and after passing through several public offices, was elected a member of the Second Chamber in 1832, in which position he vigorously opposed the politics of the governments and of the Federal Diet. In 1835, the government succeeded in obtaining a majority, but G. continued to be re-elected; until, at the close of the following year, seeing the fruitlessness of his opposition to the governmental politics, he declined re-election, and took a lease of his father's estate at Monheim, with a view to the practical study of agriculture. In 1846, G. again appeared before the public in a work against the government of electoral Hesse, which had been legislating in defiance of the constitution of the electorate. In the following year, he was elected into the Chamber again as representative of Worms, and his return to public life gave such a fresh impulse to liberal politics, that in 1848 the elections returned more opponents of the government than they had done since 1832. The life of G. became now inseparably connected with the memorable German movement of 1848. He took the lead on 27th February, by introducing a motion into the Chamber to promote the representation of the German people in the Frankfort Diet. When the preparatory convention of delegates (*das Vorparlament*) from the German states assembled at Frankfort on 31st March, G. took the most prominent part in its deliberations, and on the meeting of the parliament (28th May) (see GERMANY), he was appointed president, and continued to be re-elected every month till he was called to the perpetual presidency. Displaying more of the qualifications of a practical statesman than were possessed by most of the leading men who joined in this movement, G. struggled on amid all the divisions into which his party separated, and all the difficulties presented by the governments. But unable, on the one hand, to sympathise with the violence of the democratic party, and, on the other, to come to an understanding with the governments, he abandoned the movement altogether on the 20th May 1849. In 1850 he served as major in the Slesvig-Holstein war, and when the campaign was over, retired to the Monheim estate, which had now come into his possession by his father's death. In 1852 he sold

his estate, and removed with his family to Heidelberg, where he has since resided.

GAGING, or **GAUGING**. When this term is used without qualification, it refers specially to the gaging of the contents of casks; and in many places, the popular name for the excise officer who measures the contents of casks containing excisable liquors is 'gauger.' Sliding scales, which are graduated according to the mathematical rules for determining the solid contents of regular solids approximating to the form of the casks, are used, but considerable practice and skill are required to apply them with accuracy.

GAILLAC, a town of France, in the department of Tarn, and on the right bank of the river of that name, is situated in a fertile vine-growing district, 32 miles north-east of Toulouse. It is ill built, and has no public building of any importance except the communal college. Distilling, tanning, ship-building, and a brisk trade in wine and brandy are carried on. Pop. (1857) 5503.

GAILLARD, **GABRIEL HENRI**, a French historian, was born at the village of Ostel, near Soissons, 26th March 1726. He was educated for the bar, but soon abandoned it for literature, and afterwards turned his attention exclusively to history. His first work was entitled *Essai de Rhétorique Française à l'Usage des jeunes Démonstrateurs*, &c. (1745), and the favourable reception which it met with induced him to publish his *Poétique Française à l'Usage des Dames*. In 1757 appeared his *Histoire de Marie de Bourgogne, Fille de Charles le Téméraire*; which was followed, in 1766, by the *Histoire de François I.*, and in 1782 by the *Histoire de Charlemagne, précédée de Considérations sur la première Race, suivie de Considérations sur la seconde Race, et contenant l'Eloge du Premier Président de Lamoignon*. In a diffuse, one-sided, and rhetorical style, he represented the relations of France to England and Spain in his *Histoire de la Rivalité de la France et de l'Angleterre (1771—1777)* (which procured his admission into the French Academy), and *Histoire de la Rivalité de la France et de l'Espagne*. G. was the author of many other works. He wrote *éloges* on Malherbes (his intimate friend), Descartes, Charles V., Henry IV., Corneille, Molière, &c. He died 13th February 1806.

GAINSBOROUGH, a market-town and seaport of England, in the county of Lincoln, is situated on the right bank of the Trent, about 20 miles above the embouchure of that river in the Humber mouth, and 16 miles north-west of Lincoln. It is a well-built town, consisting mainly of one long street, running parallel with the river, which is here spanned by a fine stone bridge of three elliptical arches. It was constituted a port in 1841. The most interesting of the buildings of G. is that called the Old Hall, a curious structure composed of oak timber framing, and forming three sides of a quadrangle. It is said to have been occupied, or held in property, by the several lords of the manor of G. ever since the Saxons established themselves in this neighbourhood. Among the other public buildings are the parish church—which, with the exception of a fine old tower, dating from the 12th c., was rebuilt in 1736, and the town-hall. There are also a grammar school, established in 1589, and other educational institutions; a literary institute, and several libraries. G. is favourably situated in a commercial point of view, vessels of 200 tons being able to reach its wharfs by the river, while by means of the Keadby, the Chesterfield, and other canals, it maintains communication with the interior of the country. In 1860, 530 vessels of 25,801 tons entered and cleared this port. G. has important

manufactures of linseed oil, and carries on malting, rope-making, and ship-building extensively. Pop. (1861) of parl. borough, 6202; of township, 7700.

GAINSBOROUGH, **THOMAS**, one of the most eminent English landscape-painters, was born at Sudbury, in the county of Suffolk, 1727, and early displayed a decided talent for painting. 'Nature,' it has been said, 'was his teacher, and the woods his academy, where he would pass his mornings alone, making sketches of an old tree, a marsh, brook, a few cattle, a shepherd and his flock, or any other objects that casually came in view.' At 14 years of age, he was sent to London, where he was for some time with Mr Gravelot, the engraver, and afterwards with Hayman. At 19, he married, and set up in Bath as a portrait-painter, in which capacity he was very successful; but his genius first found adequate expression in the delineation of the rich and quiet scenery of his native country, and to this he mainly devoted himself after leaving Bath for London, in 1774. On the institution of the Royal Academy, G. was chosen one of the first members, but never took much interest in its proceedings. He died August 2, 1788, of a cancer in the neck. His last words exhibited more the enthusiasm of the painter than the logic of the theologian: 'We are all going to heaven, and Vandyck is of the party.' G.'s portraits are remarkable as 'striking likenesses,' but are not carefully finished. The best are those of the Royal Family, of Abel the composer, and Quin the actor. His fame, however, rests chiefly on his landscapes; in these, he shews himself a faithful adherent to nature, as he knew it in his own beautiful island. He is, in fact, to be regarded as the first truly original English painter, and, in the opinion of Sir Joshua Reynolds, fit to be the head of an English school. Among his finest productions are, 'The Shepherd's Boy,' 'The Fight between Little Boys and Dogs,' 'The Seashore,' and 'The Woodman in the Storm.' His most celebrated picture is 'The Blue Boy,' in the Devonshire Gallery.

GAIUS, a Roman jurist, most probably of the age of the Antonines, and the chief source of our knowledge of Roman law prior to Justinian. Considering the important place which he holds in ancient legal literature, it is strange that his personal history should be almost entirely unknown, and that almost every circumstance connected with him should be a subject of controversy. The discussion as to whether the name is properly *Gaius* or *Caius* is a mere verbal dispute; but the questions regarding his country, his condition, and even his religion, have been canvassed at considerable length. From his being uniformly called by the single appellation G., it has been inferred that he was either a foreigner or a freedman: from his familiarity with the Greek language, some have argued that he was of Greek origin; from his being cited as 'our' G. by Justinian, who was a native of Illyricum, it is argued by some that G. must have been an Illyrian by birth; while others, arguing from the same fact, and from other equally inconclusive data, have even set him down as a Christian. That the last inference is a false one, cannot admit of a moment's doubt; the others, even if it were possible to settle them definitively, are of no practical importance. As to the precise age of G., thus much is certain, that before the revision of the Roman laws, and the reform of the legal studies by Justinian, the *Institutions* of G., as well as four other of his treatises, were the received text-books of the schools of law. His *Institutions*, moreover, formed the groundwork of the *Institutions* of Justinian. From his being thus preferred to Ulpian or Papinian, it is not to be

inferred that he lived after them, but only that his work was more popular. The latest jurist whom he cites is Salvius Julianus, who lived under Hadrian, and the latest imperial edict is one of Antoninus Pius, whence it may fairly be concluded that he survived Antoninus, and probably wrote under his successor.

The works of G. were largely used in the compilation of the *Digest*, which contains no fewer than 535 extracts from his writings. The principal are, the *Edictum Provinciale*, in thirty-two books; the *Aurea*, in seven; the *Edictum Urbicum*; *On Trusts*; *On Mortgages*; and, above all, the *Institutions*, in four books. The last-named work is that by which G. is chiefly known, and it was probably the earliest complete and systematic textbook of Roman law. Although it was the basis of Justinian's *Institutions*, both as to its matter and its division, yet it was completely superseded by that work, and after a time was entirely lost, the only knowledge of it which remained being that which was gathered from the detached extracts in the *Digest*, and from the *Breviarium Alaricianum*, or code of the Visigoths, which was known to be derived from it. The recovery of this long lost work, therefore, would in any circumstances be considered a fortunate event; but the *Institutions* of G. draw additional interest from the remarkable manner in which it has been restored to literature. It had long been known that the MSS. in the library of the chapter of Verona were specially curious in the matter of jurisprudence; and in 1816, Niebuhr, while on his way to Rome, discovered, in a palimpsest MS., the later writing of which was a copy of St Jerome's epistles, portions of the work of some ancient juriconsult, the value of which he at once recognised, and the specimen page of which, as copied by him, was soon afterwards pronounced by Savigny to be a portion of the *Institutions* of Gaius. On the publication of his report, the Berlin Academy of Sciences commissioned two German scholars, Göschen and Hollweg, in 1817, to make a copy of the entire palimpsest, which consists of 127 sheets. It was a work of immense labour. The original writing had been very carefully washed, and in many pages scraped out; the lines of the second writing did not cross the original, as often happens in palimpsests, but ran in the same direction, and frequently over it; while 63 pages of the palimpsest had actually been written three times, G. having been erased to make room for a theological treatise, which in its turn was scraped out to make room for St Jerome! It reflects no small credit on the skill and patience of the copyists that they succeeded in recovering so much as nine-tenths of the entire work, which was published in 1821 by Göschen, and again, after a fresh collation of the MS. by Blume, in 1824; a third and much improved edition, by Lachmann, appeared in 1842. A comparative edition of the *Institutions* of G. and of Justinian, by Klénze and Böcking, had appeared at Berlin in 1829.

The *Institutions* of G. are divided into four books, of which the first is devoted to the law of persons, the second and third to the law of things, and the fourth to the law of actions. The first book was translated into German in 1824 by Von Brookdorff, and the entire work has been translated into French three several times—by Baullet in 1826, by Domenget in 1843, and by Pellat in 1844. In England, it has attracted but little notice, except in a few of the critical journals, and there chiefly as a literary curiosity; nor has any English translation of the work hitherto appeared.

The *Lex Romana Visigothorum*, or *Breviarium Alaricianum*, is in substance a recast of the *Institu-*

tions of G., published in 506 by Alaric for the use of the Roman subjects of the west Gothic kingdom. It is chiefly curious as illustrating the analogies and the discrepancies of Roman and barbarian law, and as supplying the germ of many of the medieval institutions by which Roman practice was supplanted. See, in addition to the editions of the *Institutions* enumerated above, Huschke, *Zur Kritik und Interpretation von Gaius Institutionen*, in his *Studien des Römischen Rechts*; also Mackeldey's *Lehrbuch des Römischen Rechts*; and Savigny, *System des heutigen Röm. Rechts*.

GALA WATER, a small river of Scotland, 21 miles in length, rises among the Moorfoot Hills in Edinburghshire, flows in a south-south-east direction through a beautiful and romantic country, and, forming in the lower portion of its course the boundary between Selkirk and Roxburgh shires, unites with the Tweed near Abbotsford.

GALA'TIO CIRCLE (see GALAXY). This circle is to sidereal what the invariable ecliptic is to planetary astronomy, the ground plane of the sidereal system.

GALACTODENDRON. See COW-TREE.

GALACTO'METER, or **LACTOMETER**, a very simple instrument for testing the richness of milk; it consists of a glass-tube, graduated to 100 parts. New milk is poured in up to the top of the graduated part, and allowed to stand; and when the cream has completely separated, the value of its quantity is shewn by the number of parts in the 100 which it occupies. Another form of instrument was invented by Döeffel, consisting of a small hydrometer with a scale two inches long divided into 20 degrees, the zero being placed at the point which the instrument sinks in water, and the 20th degree corresponding with the density 1.0393. This instrument is preferred by the continental chemists; and 14° is held to shew milk undiluted with water.

GALACZ, an important town of Moldavia, and the only port of the province, is situated on the left bank of the Danube, about three miles below the confluence of the Sereth with that river. Though it has better houses than most Moldavian towns, it cannot be said to be well built. It has numerous churches, a large bazaar, always well filled with merchandise, and a great number of store-houses for grain and other produce. It was made a free port in 1834, and is the chief entrepôt for the commerce carried on between Germany and Constantinople. Steamers passing G. ply regularly between Vienna and Constantinople, and vessels of 300 tons come close up to the town. The principal articles of export are maize, wheat, rye, tallow, wool, masts and spars, timber, and preserved meat; and the imports are chiefly British manufactures and twist, sugar, raisins, and figs, oil, coal, iron, and tobacco. In 1858, 494 laden vessels cleared at the port of Galacz. The value of the imports and exports for 1852—1855 inclusive was as follows:

Years.	Imports.	Exports.
1852,	£441,759	£547,110
1853,	559,440	648,080
1854,	121,440	148,280
1855,	634,680	1,174,380

Several British commercial houses have been established in Galacz. Pop. 40,000.

GALA'GO (*Galago* or *Otalicus*), a genus of mammalia of the Lemur family, remarkable for the great length of the hind-legs and the great size of the ears, which are membranous, and capable of being folded down as in bats. The head is rounded, the muzzle short, the eyes very large; all the feet have five toes; all the nails are flat, except those of

the first digits of the hind feet, which are armed with sharp claws; the tail is very long, and almost bushy. The species are natives of Africa and Madagascar, varying from the size of a rabbit to that of a rat, more or less nocturnal in their habits, very lively and active, feeding partly on fruits and partly on insects; one of them (*G. Senegalensis*) is known in Senegal as the *gum animal*, from living much in acacias, and feeding, or being supposed to feed, on their gum. 'These pretty animals have all

James, Narborough, Hood, Barrington, Bindlea, and Abingdon.

GALASHIE'LS, a flourishing manufacturing town, and burgh of barony, of Scotland, is situated on both banks of the Gala, about one mile from its junction with the Tweed, and is partly in Selkirkshire and partly in Roxburghshire. It is 32 miles south from Edinburgh by road, and 33½ by railway. The town is of comparatively modern erection, the greater part of it having been built within the last 20 years. The superior of the barony is Hugh Scott of Gala. The government of the town is under the Police Act of 13 and 14 Vict. cap. 23, and for all purposes of the act the burgh is held to be wholly in Selkirkshire. The town is generally well built, particularly the modern houses in the suburbs, and the new factories; but it is unhappily much crowded. The staple trade is the manufacture of woollen goods, known as 'tweeds' and plaidings. A few shawls are still occasionally made. There are 16 woollen factories, all of which, with the exception of two, are driven either by steam or steam and water-power combined. The total number of 'sets of machines' in these is 60, which turn out goods annually to the value of £300,000. Pop. within the burgh in 1861, 6500. G. has a flourishing grain market, held every Tuesday. The mills employ upwards of 2200 hands.

GALATA, a suburb of Constantinople (q. v.).

GALA'TIA was in ancient times the name of a country of Asia Minor, and was so called from a body of Gauls who settled there. In the 3d c., great hordes of Gauls, under Brennus, invaded Greece. Some of them took possession of Byzantium and the Propontis, passed the Hellespont on the invitation of Nicomedes, king of Bithynia, in the year 278 B.C., subdued Troas and the north of Phrygia, and were first checked by Attalus, king of Pergamus, in a great battle about the year 239 B.C., and compelled by him to settle permanently within certain limits. The state of G., which hitherto had had no accurately defined boundaries, was now confined between Paphlagonia, Pontus, Cappadocia, Lycania, Phrygia, and Bithynia. It was also called Gallogræcia, and was peopled by numbers of Phrygians, Greeks, and Paphlagonians, as well as Gauls or Celts. The form of government was at first purely aristocratic, but at a later period the twelve tetrarchs who shared the government among them, in conjunction with a senate of 300 members, succeeded in making their dignity hereditary. At length one of them (30 B.C.), supported by Pompey, assumed the title of king. After his death, the kingdom descended to Amyntas, but was shortly after conquered by the Romans, and converted into a Roman province, divided under Theodosius into *Galatia prima*, with the capital Ancyra, and *Galatia secunda*, with the capital Pessinus. The majority of the Gauls of G. retained their old Celtic language as late as the time of Jerome (4th c.), who says that they spoke the same dialect as the people about Treves; and as Jerome had himself lived there, and was a good scholar, he may be regarded as an authority on the subject. G. was twice visited by the Apostle Paul.

GALA'TIANS, EPISTLE TO THE. This epistle was written by the Apostle Paul during his residence at Ephesus, probably about the year 56 A.D., and is generally reckoned the third or fourth of the Pauline epistles in the order of time. The circumstance which called it forth was the diffusion throughout the Galatian churches, of Judaistic practices and notions, chief among which stood the famous rite of circumcision, regarded by Paul as the symbol of all that was exclusive, external, merely

Galago Monoli (from Routledge's *Natural History*).

the activity of birds, leaping from bough to bough. They watch insects flitting among the leaves, listen to the fluttering of the moth as it darts through the air, lie in wait for it, and spring with the rapidity of an arrow, seldom missing their prize, which is caught by their hands.' When they leap, they always seize with their hands the branch on which they intend to rest. They make nests of grass and leaves for their young in the branches of trees. They are a favourite article of food in Senegal.

GALANGALE (*Alpinia*), a genus of plants of the natural order *Zingiberaceæ* or *Scitamineæ*, having perennial stems with terminal inflorescence and succulent fruit. The root-stocks possess stimulating properties similar to those of ginger. The true G. is the produce of *A. galanga*, a native of the Eastern Archipelago, and cultivated there; having a stem six or seven feet high, broad leaves, and a branched panicle of greenish-white flowers. The root-stock, when young, yields a kind of arrow-root, and is used as an article of food; it acquires pungency and aromatic properties as it becomes older. G. is much used in the East for the same purposes as ginger; it is also used to a very considerable extent on the continent of Europe, but very little in Britain. Inferior kinds are obtained from several species of *Alpinia*; and from a plant of an allied genus, *Kaempferia Galanga*, the root-stock of which is commonly sold in the bazaars of Northern India.

GALA'NTHUS. See SNOW-DROP.

GALAPA'GOS ISLANDS (so named from *gald-pago*, the Spanish word for *tortoise*) are a volcanic group in the Pacific, situated on or near the equator, and in long. between 89° and 92° W. They are thirteen in number, the largest measuring 60 miles by 15, with an elevation of 4000 feet. They can hardly be said to be peopled, being visited chiefly for their turtles, which are of enormous size. The ten principal members of the cluster are Albemarle, Indefatigable, Chatham, Charles,

ethical, and therefore thoroughly antagonistic to the universality of the gospel. Paul had himself been the first to preach Christ in this region, and as the majority of his converts were Gentiles, it would naturally vex him all the more keenly to see them lapsing into practices inconsistent with their new faith, and for which they had not even the excuse that might have been proffered for the Jews, viz., that antiquity had made such customs venerable. It would also appear that the Judaizing adversaries of Paul had been circulating injurious reports concerning himself, hinting that he was no divinely appointed apostle, but at best a mere messenger of the church of Jerusalem, that he had quarrelled with Peter, the great apostle of the circumcision, and that he could play 'fast and loose' on this very question of circumcision itself. In his reply to the underhand attacks of his calumniators, Paul asserts the truth of his gospel, passionately declaring that he would pronounce a curse on the very angels from heaven, if they would dare to preach another, vindicates his apostleship, and gives the true version of the story of his variance with Peter. He then proceeds to discuss the relation of Judaism to Christianity, and closes with a series of exhortations and admonitions, the first of which is the well-known 'Stand fast therefore in the liberty wherewith Christ hath made us free, and be not entangled again with the yoke of bondage' (v. 1). The commentaries on Galatians are very numerous; among others may be mentioned those of Luther, Winer, Rückert, De Wette, Meyer, Ellicott, and Alford.

GALATINA, S. PIETRO IN GALATINA, a town in the south of Italy, in the province of Otranto, is situated in a fertile but unhealthy plain, 13 miles south of the town of Lecce. Some maintain that it is a very ancient place, but there seems no historical ground for the assertion. G. is a thriving commercial town, and possesses fine public edifices and handsome churches. Pop. 8400. Raimondo Orsino, Prince of Taranto, and Lord of Galatina, surrounded the town with ramparts, as a tribute to the citizens for having ransomed him from the Turks for 12,000 ducats.

GALATONE, a very ancient town in the south of Italy, in the province of Otranto, about nine miles north-east of Gallipoli, is situated in a very rich but insalubrious plain. Pop. 5500. In the struggle between Joanna Queen of Naples and Alfonso, G., having declared for the former, was besieged by Alfonso, and its ramparts destroyed. It has been possessed by several illustrious families.

GALAXY, THE (Gr. *gala*, *galaktos*, milk), or the Milky-Way, is the great luminous band which nightly stretches across the heavens from horizon to horizon, and which is found, when carefully traced, to form a zone, completely encircling the whole sphere almost in a great circle. At one part of its course, it opens up into two branches, one faint and interrupted, the other bright and continuous, which do not reunite till after remaining distinct for about 150°. This great zone has occupied the same position in the heavens since the earliest ages. The reader will find its course mapped out on any celestial globe, and a verbal account of it in Sir John Herschel's *Outlines of Astronomy*, by which he may test the accuracy of the chart. That course, as traced by the naked eye, following the line of its greatest brightness, conforms nearly to that of a great circle, called the Galactic Circle, inclined at an angle of about 63° to the equinoctial, and cutting that circle in 6 hours 47 minutes, and 12 hours 47 minutes right ascension. Throughout the space where, as above stated, it is divided into two

branches, this great circle is intermediate to the two, lying nearer that which is the brighter and more continuous. The most casual survey of the Galaxy shows that it is wanting in regularity of outline. Besides the two great branches into which it divides, it has many smaller ones which spring out from it. At one point, it diffuses itself very broadly, and opens out into a fan-like expanse of interlacing branches nearly 20 in breadth. At the same point the branches terminating abruptly, a wide gap presents itself in the zone, on the opposite side of which it recommences its course with a similar assemblage of branches. At other points, its course is described by Sir John Herschel as 'irregular, patchy, and winding;' while at more than one point, in the midst of its brightest parts, broad dark spaces occur. One of these, known from early times among navigators as the 'coal-sack,' is a singular pear-shaped vacancy of about 8° in length, and 5° broad, occurring in the centre of a bright area overlying portions of the constellations of the Cross and Centaur. The 'coal-sack' occupies about half the breadth of this bright space, and presents only one star visible to the naked eye, though it contains many telescopic stars. Its blackness, which attracts the most superficial observer, is thus due to the contrast with the brilliant ground by which it is surrounded.

The Galaxy was examined by Sir William Herschel with his powerful telescope, and found to be composed entirely of stars. How a collection of stars can assume such appearances as are presented in the Galaxy, is explained in the article Stars (q. v.).

GALBA, SERVITIUS SULPICIUS, Roman emperor from June 68 A.D. to January 69, was born 24th December 3 B.C., of a respectable family. He was raised to the consulship in 33 A.D.; and in the administration of the province of Aquitania under Tiberius, of Germany under Caligula, of Africa under Claudius, and of Hispania Tarraconensis under Nero, he distinguished himself for bravery, strictness, and justice. His friends had urged him, on the death of Caligula, to take possession of the throne, but he continued faithful to Claudius, and therefore stood high in his favour. In 68, Julius Vindex rose with the Gallic legions against Nero, and called on G. to assume the imperial dignity, and thus rid the earth of its oppressor. G., who had been informed that Nero was contriving his death, came forward against him at first as the legate of the Roman people, and it was only when he heard of Nero's death that he proceeded to Rome to take possession of the throne offered him by the Prætorians. G. was now upwards of 70 years old, and it soon appeared that his character had deteriorated, as, indeed, had already been manifested in his later administrations. Indulgence to greedy favourites, ill-timed severity, above all, avarice, which led him to withhold the usual donatives to the troops, made him unpopular. The legions in Upper Germany called on the Prætorians to choose another emperor; G. thought to soothe them by adopting Piso as his coadjutor and successor; but he thus offended Otho, who, as administrator of Lusitania, had supported G., and looked to be rewarded. The Prætorians, who had received no donative on occasion of Piso's adoption, were easily excited to insurrection by Otho, and the emperor having gone out to quell the rebellion, was cut down by the soldiers as he crossed the forum.

GALBANUM, a gum resin used in medicine in the same cases as assafoetida. It is principally employed in chronic catarrh, and has been given (especially by the Germans) in amenorrhœa and chronic rheumatism. It is generally administered

in the form of the compound *galbanum pill*, which contains galbanum, sagapenum, assafœtida, myrrh, and soft soap. It is sometimes applied externally in plasters as a mild stimulant in indolent swellings. It is brought from the Levant, and appears in commerce either in tears or in large masses. It is soft, ductile, whitish, or, when long kept, yellowish in colour; has a peculiar balsamic odour, and an acrid, bitter taste. Although it has been known from the earliest ages, and is mentioned by Moses (Exod. xxx. 34) under the name *chelbanah* (translated galbanum in the English Bible), it is still uncertain from what plant it is derived. *Galbanum officinale*, *Ferula galbanifera*, and *Opoidia galbanifera*, all of the natural order *Umbelliferae*, have, on various grounds, been supposed to be the source of galbanum; and the confidence with which they have been so represented has perhaps prevented travellers from making that inquiry into the subject which otherwise they might have made. It is highly probable that galbanum is the produce of an umbelliferous plant. *Bubon Galbanum*, a plant of this order, found at the Cape of Good Hope, yields a gum resin very similar to galbanum.

GALE, or SWEET GALE (*Myrica gale*), a small shrub of the same genus with the North American Candleberry (q. v.), and very nearly allied to it—a native of all the northern parts of the world, growing in bogs and in moist gravelly soils, very

political offices, and was at last made Bishop of Münster, 14th November 1650. The vigour of his administration immediately began to appear in restoring church-discipline, in allaying a famine which prevailed at the time, in promoting trade, and ridding the country of foreign troops. He soon, however, fell into disagreements with the inhabitants of Münster, who, on applying to Holland, received 25,000 guilders to assist them against him; but with the support of 1200 cavalry from the emperor, the bishop reduced the town into submission in 1660, and continued to maintain his ascendancy by severe measures. In 1664, on being appointed, along with the Markgraf of Baden, director of the military affairs of the Rhenish alliance, he proceeded with most of his own troops to the seat of the war against the Turks. After his return, he entered into alliance with England against the Netherlands, but the war was soon concluded, in consequence of the treaty brought about by Louis XIV. in 1666, according to which the States-general promised the restoration to the bishop of all his lands. A dispute, however, afterwards arose, and in 1672, G. again went to war with the Dutch in alliance with France. After some successes obtained in union with Turenne, he suffered such a heavy loss during the siege of Coevorden, by a storm which placed his camp under water, that he willingly concluded a treaty with the allies in 1674, in which he promised to give up all his conquests in the Netherlands. In the following year, he changed sides, and entered into alliance with the emperor against the French. By taking part, also, with the king of Denmark and the elector of Brandenburg in the war with Sweden, he added the duchy of Bremen and other places to his possessions. In 1678, he obtained considerable pecuniary compensation for being drawn into war with East Friesland; but while the peace negotiations were going on he died, 19th September. The family of G. is one of the oldest in Westphalia, and is at present represented by Count Matthias von Galen, whose brother, Count Ferdinand, has distinguished himself in the Prussian service as an able diplomatist.

GALENA, or LEAD-GLANCE, a mineral which is essentially a sulphuret of lead, the proportions being 13·3 sulphur and 86·7 lead; but usually containing a little silver, and sometimes copper, zinc, antimony, or selenium. It is of a lead-gray colour, with a metallic lustre, is found massive, or sometimes granular, or crystallised in cubes or octahedrons. It is very easily broken, and its fragments are cubical. It occurs in veins, beds, and imbedded masses, often accompanying other metallic ores, in primitive and secondary rocks, but most of all in what is known as transition or mountain limestone. It is found very abundantly in some parts of Britain. Almost all the lead of commerce is obtained from it. It sometimes contains so much silver, that the separation of that metal is profitably carried on. The lead is extracted from it by a very simple process. See LEAD.

GALENA, a thriving city of the United States, North America, is situated in the north-west corner of the state of Illinois, on both sides of the Galena river, and three miles from the junction of that stream with the Mississippi. It is 450 miles north of St Louis, and 250 miles north-north-west of Springfield. The city, owing to the irregularity of the ground on which it is built, has a bold and picturesque appearance. In and around the town, high bluffs, rising frequently to a height of more than 200 feet, everywhere occur. The streets rise in terraces, one above another, communicating by flights of steps; and among the public buildings are numerous churches and schools, a United States

Gale (*Myrica gale*):

a, a scale of the catkin, inside; b, stamens; c, an anther.

abundant in some parts of Britain, but very local. It has small lanceolate slightly serrated leaves, which are sprinkled with resinous dots, and emit a most agreeable fragrance. Its berries are small, and sprinkled with golden resinous dots. The northern nations formerly used this plant instead of hops. The leaves were also employed as a remedy for itch, and have the power of keeping away moths. A decoction of them is efficacious against bugs. By distillation they yield a yellow essential oil. In the Highlands of Scotland, beds are often made of the twigs of gale, which is there called *noth*.

GALEN, CHRISTOPH BERNHARD VON, Bishop of Münster, and one of the greatest generals of his time, was born at Bispink, in Westphalia, 15th October 1600. After completing his studies in the Jesuit college of Münster, and at the universities of Cologne, Mayence, Louvain, and Bordeaux, he held several

marine hospital, and a custom-house. G. owes its origin and rapid growth to the rich mines of lead which surround it. In 1857, 34,183,250 lbs. of lead, valued at 801,324 dollars, were exported from Galena. Copper is also found, though not in great quantity. G. has manufactures of pottery, soap, and candles; it has also lead furnaces, iron foundries, and machine-shops; breweries, carriage-manufactories, and numerous mills. Besides lead, it exports horses, cattle, pork, and agricultural produce. In 1819 the first house was built at G.; in 1859 it contained 14,000 inhabitants.

GALENICAL, GALENIST, two words having reference to the controversies of the period of the revival of letters, when the authority of Galen was strongly asserted against all innovations, and particularly against the introduction of chemical, or rather *alchemical* ideas and methods of treatment into medicine. The Galenists adhered to the ancient formulas, in which drugs were prescribed, either in substance or in the form of tinctures and extracts, &c.; while the chemists professed to extract from them the essences, or quintessences (*quinta essentia*, the *fifth* essence, supposed to be particularly pure, as requiring five processes to extract it), i.e., substances in small bulk, presumed to contain the whole virtues of the original drugs in a state of extreme concentration, or purified from all gross and pernicious, or superfluous matter. There can be no doubt, now-a-days, that upon both sides of this controversy there was a great deal of blind error and rash dogmatism, which on the side of the chemists, as in Paracelsus, took the form of quackery and mysticism; while the Galenists, on the other hand, were the supporters of tradition and all its encumbrances, and too often the envenomed partisans of old blunders or misconceptions, as opposed to new forms of truth. But the original idea of those who afterwards became identified with the sect of the Galenists, was rather to free the ancient medicine from the irrational dogmas and methods of cure with which it had been overlaid by the Arabians and the monks, than to insist upon mere antiquity, or upon Galen's authority in particular, as demanding the blind assent of mankind in opposition to new truth. Now that chemistry has really given us new methods of preparing drugs, which supersede many of those that have been used from time immemorial, it is still customary with some to call preparations by the latter methods *Galenical*, as contrasted with the crystalline alkaloids, or the perfectly pure acids and bases, which contain the virtues of most of our most valuable vegetable medicines. See **GALEN**, **PARACELUS**, **ALCHEMY**, and the several articles on the *materia medica*.

GALENUS, **CLAUDIUS**, commonly called **GALEN**, a very celebrated physician, born at Pergamus, in Mysia, 130 A.D. In his 17th year, his father, Nicon, who had hitherto destined him to be a philosopher, in consequence of a dream, chose for him the profession of medicine. This subject he first studied at Pergamus, afterwards at Smyrna, Corinth, and Alexandria. He returned to his native city in his 29th year, and was at once appointed physician to the school of gladiators. In his 34th year, he went to Rome, where he stayed for about four years, and gained such a reputation, that he was offered, but declined, the post of physician to the emperor. He returned to his native country in his 38th year, and had scarcely resumed his ordinary course of life, when he received a summons from the Emperors M. Aurelius and L. Verus to attend them in the north-eastern frontier of Italy, whither they had gone to make preparations for a war with the northern tribes. He joined the camp towards

the end of the year 169; but a pestilence breaking out, the emperors and their court set off for Rome, whither G. accompanied or followed them. On the return of M. Aurelius to the seat of war, G. obtained permission to be left at Rome, alleging that such was the will of Æsculapius, as revealed to him in a dream. How long G. stayed at Rome on this second occasion is not known, but we ascertain from his works that he attended M. Aurelius and his two sons, Commodus and Sextus, and that at about the end of the 2d c. he was employed to compound a celebrated medicine called *Theriaca* for the Emperor Severus. If the statement of one of his Arabic biographers be correct, who expressly says that G. was only twice at Rome, we must infer that the greater part of his middle and more advanced life was spent in that city. The place and date of his death are not known with certainty, but it is believed that he died in Sicily about the year 201.

The works that are still extant under the name of G. consist, according to Choulant, in his *Handbuch der Bücherkunde für die ältere Medicin*, of 83 treatises acknowledged to be genuine; 19 whose genuineness has been questioned; 45 undoubtedly spurious; 19 fragments; and 15 commentaries on different works of Hippocrates. Besides these, he wrote a great number of works whose titles only are preserved, and altogether it is believed that the number of his distinct treatises cannot have been less than 500.

We may divide his works into (1) those on anatomy and physiology; (2) those on dietetics and hygiene; (3) those on pathology; (4) those on diagnosis and semeiology; (5) those on pharmacy and *materia medica*; (6) those on therapeutics, including surgery; (7) his commentaries on Hippocrates; and (8) his philosophical and miscellaneous works. We have most of these works in Greek, the language in which they were originally written; some are, however, preserved only in Latin translations, and a few only in Arabic. His most important anatomical and physiological works are—*De Anatomicis Administrationibus*, and *De Usu Partium Corporis Humani*. Of the latter, Dr Greenhill (Smith's *Dictionary of Greek and Roman Biography*) remarks that 'it is no less admirable for the deep religious feeling with which it is written, than for the scientific knowledge and acuteness displayed in it.' For a good general account of G.'s anatomical and physiological knowledge, we may refer to a memoir published by the late Professor Kidd of Oxford in the sixth volume of *The Transactions of the Provincial Medical and Surgical Association*, entitled 'A Cursory Analysis of the Works of Galen, so far as they relate to Anatomy and Physiology,' and Daremberg's *Exposition des Connaissances de Galien sur l'Anatomie, la Physiologie, et la Pathologie du Système Nerveux* (Paris, 1841), may also be consulted with advantage. His anatomical and physiological writings are by far the most valuable of his works. They contain undoubted evidence of his familiarity with practical anatomy; but whether he derived his knowledge from dissections of human bodies or those of the lower animals, is uncertain. The latter is the most probable view—(1) because he frequently recommends the dissection of apes, bears, goats, &c.; and (2) because he mentions, as something extraordinary, that those physicians who attended the Emperor M. Aurelius in his wars against the Germans had an opportunity of dissecting the bodies of the barbarians. Much curious information regarding G.'s views on dietetics and hygiene will be found in Adams's *Commentary on the First Book of Paulus Ægineta*. His pathology was very speculative and imperfect. In his diagnosis and prognosis, he laid great stress on the

pulse, on which subject he may be considered as the first and greatest authority, for all subsequent writers adopted his system without alteration. He likewise placed great confidence in the doctrine of critical days, which he believed to be influenced by the moon. In materia medica, his authority was not so high as that of Dioscorides. Numerous ingredients, many of which were probably inert, enter into most of his prescriptions. He seems to place a more implicit faith in amulets than in medicine, and he is supposed by Cullen to be the author of the anodyne necklace, which was so long famous in England. We cannot attempt to enter into his system of therapeutics. We may, however, observe, that his practice is based on two fundamental principles—(1) that disease is something contrary to nature, and is to be overcome by that which is contrary to the disease itself; and (2) that nature is to be preserved by that which has relation to nature. Hence arise two general indications of treatment—the one taken from the affection contrary to nature, which affection requires to be overcome; the other from the strength and natural constitution of the body, which requires to be preserved.

Before G.'s time, the medical profession was divided into several sects, who were always disputing with one another; as, for example, the Dogmatici, Empirici, Eclecticci, Pneumatici, and Episyntetici. After his time, all these sects seem to have merged in his followers. The subsequent Greek and Roman medical writers were mere compilers from his writings; and as soon as his works were translated (in the 9th c.) into Arabic, they were at once adopted throughout the East, to the exclusion of all others. In short, G. reigned paramount throughout the civilised world till within the last 300 years. The records of the London College of Physicians afford a striking illustration of this fact, in so far as England is concerned. In 1559, Dr Gaynes 'was cited before the college for unpugning the infallibility of Galen. On his acknowledgment of his error and humble recontrition, signed with his own hand, he was received into the college.'

The Greek text has been published four times. The first edition was the Aldine, printed in 1525, in 8 folio volumes; the latest and most accessible edition is that of C. G. Kühn, in 20 octavo volumes, the publication of which extended from 1821 to 1833. A good critical edition is still required.

GA'LERITES (*galerus*, a cap), a genus of fossil sea-urchins, peculiar to and abundant in the Chalk measures. The generic name, as well as that popularly given to them in the districts where they abound,

via, 'Sugar-loaves,' is descriptive of the elongated and more or less conical shape of their shell. The body in breadth is nearly circular or polygonal. The under surface is entirely flat, and has the mouth placed in its centre,

Galerites Albogalerus. with the vent near the margin. There are five avenues of pores reaching from the mouth to the summit. These fossils are often found silicified. The species figured is one of the most abundant; it has received its specific name from its resemblance to the white caps worn by the priests of Jupiter.

GALE'RIUS, VALERIUS MAXIMIANUS, a Roman emperor of humble parentage, was born near Sardica, in Dacia, entered the imperial army, and rose from one grade of military rank to another,

until Diocletian conferred on him, along with Constantius Chlorus, the title of Cæsar (292 A.D.), and gave him his daughter in marriage. On the abdication of Diocletian (305 A.D.), he and Constantius became *Augusti*, or joint-rulers of the Roman empire. On the death of Constantius at York (306 A.D.), the troops in Britain and Gaul immediately declared their allegiance to his son, Constantine (afterwards Constantine the Great), much to the chagrin of G., who expected the entire sovereignty of Rome to fall into his hands. He died in 311 A.D. G. was a brave soldier and a skilful commander, but appears to possess no other claims to the respect of posterity. He hated the Christians 'with a perfect hatred;' and it is believed that it was he who forced Diocletian to issue his famous edict against them, which caused the *last* of the imperial persecutions. His mother, an ignorant pagan fanatic, is said to have exercised much influence over him; but it is highly probable that his treatment of the adherents to the Christian faith was also determined by a politic opposition to Constantius and his son, who tolerated, and even respected the new opinions and practices.

GALIA'NI, FERDINANDO, an Italian savant, was born in Chieti, a province of the Abruzzi, in 1738, and exhibited at an early period an extraordinary aptitude for learning. Philosophy, history, archaeology, and more especially the science of political economy, were his favourite studies; but, nevertheless, he first attracted notice by a clever squib on the death of the public executioner. This consisted of a collection of essays eulogistic of the deceased, in which the style of the president and leading members of the Neapolitan Academy was admirably imitated. It was entitled, *A Collection of Papers in honour of Domenico Jannaccone, Public Executioner, revised and issued by the President of the Academy, Gian Antonio Sergio, Advocate*, and excited universal comment in Naples. The young delinquent was condemned to a period of seclusion, prescribed for penitential exercises. His next publication, *Della Moneta*, was more deserving of his pen, and evinced his great learning and powers of reflection. It must be regarded as a valuable contribution to the science of political economy. The leading principle which it seeks to establish is, that coin is a merchandise, and that its value and interest ought to be left free like other goods. By the adoption of the sage monetary doctrines propounded by an economist, who barely numbered 20 years, the financial ruin of Naples is said to have been then averted. In 1751, he visited the chief cities of Italy, and was everywhere honourably received. From Pope Benedict XIV. he received repeated proofs of favour and confidence. Having contracted during his travels intimate friendships with some of the most famous naturalists of his country, he immediately entered with enthusiasm into their pursuits, and on his return to Naples collected a rich assortment of the stones and volcanic matter of Vesuvius, which he subsequently presented to the pope, accompanied by a learned thesis. On one of the stone specimens, he engraved the following suggestive inscription, '*Benignissime pater, fac ut lapides isti panes fiant*;' and received, by way of answer, the rich prebend of Amalfi, for which he had previously qualified himself by entering into holy orders. In 1759, he became secretary to the Neapolitan Embassy at Paris, where his wit, vivacity, and learning made him a universal favourite. In 1767, he visited England, whose social and political institutions he studied deeply. On his return to Parma, he wrote another treatise on political economy, entitled *Dialoghi sul Commercio del Grano* (Dialogues upon the Trade in Corn), in which he argues against both

the extreme protectionists and the pure free-traders. Being recalled to Naples, he was successively appointed to various posts of trust and importance. He died at Naples in 1787, leaving behind him rare collections of musical MSS., ancient coins, sculptures, medals, precious stones, cameos, &c.

GALICIA, formerly a province in the north-west of Spain, with an area of 11,195 square miles, and a population of about 1,776,879 souls, has been divided, since 1833, into the minor provinces of Coruña, Lugo, Orense, and Pontevedra. The country is mountainous, being covered by several offsets of the Asturian chain, rising in their highest peaks to the height of about 6000 feet. Capes Ortegal and Finisterre project into the Atlantic. The numerous rivers form *Rias*, or small estuaries at their mouths, and afford secure havens and roads. The principal river is the Minho, which, with its feeders, the Sil and the Avia, is navigable as it approaches the sea. G. is one of the most fruitful portions of Europe, and has a mild nourishing climate. Rich meadows and dense forests occur everywhere, but the soil is more suited to the cultivation of garden-produce than of corn. The inhabitants, who are called Gallegos, are a robust, vigorous, and industrious race. They visit various parts of the country, and are employed in Madrid as water-carriers, porters, &c. Fishing and navigation are the occupations most largely followed. Linen manufactures have been recently established. The principal towns are St Jago di Compostella, and the two strongly fortified seaports Coruña and Ferrol.

GALICIA, a crown-land belonging to the Austrian monarchy, including the former kingdoms of Galicia and Lodomeria, the duchies of Auschwitz and Zator, and the grand-duchy of Cracow. It is bounded on the N. by Poland and Cracow, on the E. by Russia, on the S. by the Bukovina and Hungary, and on the W. by Silesia. It has an area of 29,941 square miles, and its population in 1857 amounted to 4,597,470, the great body of whom are Roman Catholics. The country is a high terrace, situated at the northern base of the Carpathians. The northern portion forms an extensive plain, broken only by low ranges of hills. There are many large rivers—those in the west being feeders of the Vistula, those in the east, of the Danube and Dniester. The climate of G. is colder than that of any other portion of the Austrian empire; the soil, with the exception of some sandy and marshy districts, is fertile, and produces corn, which is exported in considerable quantities. Flax, hemp, tobacco, hops, &c., are likewise cultivated. Horses, cattle, and sheep are raised in considerable numbers. Wolves and bears are still found in the mountainous districts. Salt is the most important mineral. Industry has lately made marked progress. Commerce is on the increase. The roads are good; and a railway has been recently constructed. For administrative purposes, G. has been divided into three governments—viz., Lemberg, Cracow, and Stanislawow. G. takes its name from the old fortress and town of Halicz, on the Dniester. The original Slavonic inhabitants, the Ruthenes, were, towards the end of the 9th c., conquered by the Russians of Kiev. The western portion of the country had already become dependent on Poland, and afterwards on Hungary. In 1382 it was restored to Poland, and continued to belong to that country till the partition of 1773, when G. became one of the crown-lands of Austria. In 1846, Cracow, with the territory belonging to it, was, by a treaty of the three powers (Austria, Russia, and Prussia), given up to the emperor of Austria, and by him annexed to the crown-land of Galicia.

GALICZ. See **HALICZ**.

GALILEE, the name applied to a porch or chapel placed at the entrance to a church, beyond which women were not permitted to pass. In abbeys, for example, the monks came to the galilees to see their female relatives. A portion of the nave was sometimes marked off by a step, or, as at Durham, by a line of blue marble, to mark the boundary to which women were limited. There are fine specimens of galilees at Lincoln, Ely, and Durham.

GALILEE (Heb. *Galil*, a 'circle' or 'circuit') is the name originally applied to a small district belonging to the Jewish tribe of Naphtali (see Josh. xx. 7). Here were situated the 20 towns which Solomon gave to Hiram, king of Tyre, for his assistance in building the temple. Phœnician colonies, in consequence, appear to have established themselves here, or the towns perhaps reverted by some chance to their original Canaanitish occupants, for at a later period we find Isaiah (ix. 1) speaking of the district as 'Galilee of the nations.' These 'nations,' or Gentiles, appear to have greatly increased in numbers, and to have finally spread themselves over all the surrounding country, until, in the time of our Lord, the name 'Galilee' embraced the whole northern portion of Palestine from the Mediterranean to the Jordan. As early as the time of the Maccabees (book I. chap. v. verses 20—23), the number of Jews in G. was very small; Strabo, a contemporary of Christ, states that in his day it was mainly inhabited by Syrians, Phœnicians, and Arabs, to whom Josephus adds Greeks. The principal towns at the dawn of Christianity were Tiberias, Tarichæa, and Sepphoris; those that figure in the gospels are Cana, Capernaum, Nazareth, and Nain. The Jewish inhabitants of G. spoke a broader and coarser dialect than their southern brethren of Judæa, and were held in low estimation by the latter, partly on account of their more liberal sentiments in regard to religion. It has been thought likely that this liberality, the existence of which is indisputable, was owing to their intercourse with their different heathen neighbours. Every one of the disciples was a Galilean either by birth or residence, and consequently may not have been a Jew at all in the strict sense of the term; i.e., in being able to boast of having 'Abraham for his father.' The first three gospels are chiefly taken up with records of the Saviour's ministrations in this province. After the destruction of Jerusalem, the despised G., as if retributively, became the refuge of the proud doctors of Jewish law, and the city of Tiberias the seat of Rabbinical learning. The ruins of many fine synagogues are still extant in the old towns and villages of this region. At present, G. belongs to the pashalik of Damascus, in the Turkish province of Syria or Soristan, and, as of yore, is remarkable for its beauty and fertility. It still has a considerable number of Jewish inhabitants.

GALILEI, **GALILEO**, the creator of experimental science, was born at Pisa on the 15th of February 1564. He belonged to a Florentine family more ancient than opulent. G., by desire of his father, exclusively directed his early studies to medicine, and the prevailing Aristotelian philosophy, the dogmas of which he soon ventured to disbelieve and despise. At the age of eighteen he made one of his most important discoveries. Happening on one occasion to observe, in the cathedral of Pisa, the oscillation of a lamp casually set in motion, G. was struck with the apparent measured regularity of its vibrations; and having tested the correctness of this observation by

comparing the beat of his own pulse with the action of the pendulum, he concluded that by means of this equality of oscillation a simple pendulum (q. v.) might become an invaluable agent in the exact measurement of time. This discovery he subsequently utilised by the successful application of the pendulum in constructing a clock for astronomical purposes. G.'s irrepressible bias towards mechanical constructions and experimental science received a new impulse from his intercourse with a friend of his father's, Ostilio Riccio, professor of mathematics, who, in compliance with the youth's entreaties, initiated him into the principles of mathematics. Such was G.'s absorption and delight in his new studies, that his father at length sanctioned his abandonment of the art of medicine, in order that he might concentrate his powers on his chosen sciences. The first fruit of his geometrical investigations was the invention of a hydrostatic balance, by which the specific gravity of solid bodies might be ascertained with the nicest accuracy. In 1589, the fame of G.'s extraordinary learning having reached the Grand Duke of Tuscany, this enlightened prince appointed him professor of mathematics in the university of Pisa, where he covertly inculcated many of those great innovations in physical science which have since added such lustre to his memory. About this period he turned his attention to the then very imperfectly comprehended laws of bodies in motion; and in opposition to all received systems, he propounded the novel theorem, that all falling bodies, great or small, descend with equal velocity. This soon led him to the discovery of 'the three laws of motion,' and the law regulating the motion of falling bodies, which is expressed by the formula $S = \frac{1}{2} ft^2$. This theory of falling bodies was proved correct by several experiments which were made from the summit of the leaning tower of Pisa, greatly to the chagrin of the Aristotelians, whose enmity to G. now grew more decided. In consequence, he deemed it prudent to relinquish his chair at Pisa, and retired to Padua, where he accepted the offer of the Venetian senate to lecture on mathematics in the university for the space of six years. It is also said, however, that G. lost his chair at Pisa, from having ridiculed the mechanical pretensions of John de Medici, son of Cosmo I. G.'s engagement at Padua was eventually prolonged to the term of 18 years; but so urgent was his desire to return to his birthplace, that he sought a restoration to his former post at Pisa, and was gratified by an assent being eagerly accorded by Cosmo de' Medici, with exemption from any but a voluntary exercise of the duties of the professorship. During his sojourn at Padua, his course of lectures enjoyed extraordinary popularity; crowds of pupils flocked to hear him from all parts of Europe; and he was the first to adapt the Italian idiom to philosophical instruction. Among the various and noble discoveries with which he enriched science, may be noticed a species of thermometer, a proportional compass or sector, and more important than all, the construction of the refracting telescope for astronomical investigation. In 1609, he offered his first complete telescope to the Doge of Venice, Leonardi Deodati, by whom it was tested from the tower of St Mark with equal surprise and delight. In the same year he constructed a microscope; and then this indefatigable interpreter of the mysteries of nature commenced his astronomical researches by means of his own telescope. He speedily concluded that the moon, instead of being a self-luminous and perfectly smooth sphere, owed her illumination to reflection, and presented an unequal surface, deeply furrowed by valleys and mountains

of great extent. The Milky Way he pronounced a track of countless separate stars; and these discoveries were crowned by a still more important series of observations, which led to the discovery of the four satellites of Jupiter on the night of the 7th of January 1610 (though it was not till the 13th of the same month that he came to the conclusion that they were satellites, and not fixed stars), which he named the Medicean stars, in honour of his constant protectors in that family. He also was the first to note movable spots on the disc of the sun, from which he inferred the rotation of that orb. Encircled by the lustre of these sublime discoveries, he departed from Padua, and returned to Tuscany in 1610, where renewed quarrels with the Aristotelians disquieted and embittered his existence. In 1611, he visited Rome, and was received with great distinction, being enrolled a member of the Lincei Academy; but four years later, on repeating the visit, his reception was widely different, as by that time in his work on the solar spots he had openly advocated the Copernican system, and was in consequence denounced as a propounder of heretical views. He repaired again to Rome, to demand an experimental inquiry into the soundness of his views; but the grand duke apprehending inquisitorial dangers for his favourite, summoned him back to Tuscany; at the same time the pope, through the famous Cardinal Bellarmine (a sincere friend of G.'s), commanded him to abstain from all future advocacy of his heretical doctrines. Some time after, he wrote his most famous work in the form of a dialogue between three fictitious interlocutors, the one in favour of the Copernican system, the second an advocate of the Ptolemaic, and the third a rabid supporter of the Aristotelian school. Of course, the whole weight of the *proof* falls into the Copernican scale; and nothing can exceed the classic beauty of this composition, or the compactness of the chain of its argument. In 1630, G. contrived to obtain the papal imprimatur, which was subsequently revoked; but having got a similar authorisation at Florence, he published, in 1632, this exponent of his opinions under the title of *Un Dialogo intorno i due Massimi Sistemi del Mondo*. Hardly had the work been issued, when it was given over to the jurisdiction of the Inquisition. Pope Urban, previously Cardinal Barberini, and, until now, a friend and eulogist of G., was led to believe that G. had satirised him in this work under the title of *Simplicio*, as one who is careless about scientific truth, and who timidly adheres to the saws of antiquity. He resolved to punish the audacious philosopher. In spite of his 70 years and heavy infirmities, G. was summoned before the Inquisition to answer for his heresies. After a wearisome trial and incarceration, his judges condemned G. to abjure by oath on his knees the sublime truths of his scientific creed. This he was weak enough to do. His latest biographer, M. Philartès Charles, however, denies that G. was put to the torture, and pronounces the letter of G. to Reinecci, from which Tiraboschi quotes to prove it, a forgery. His famous whisper, *E pur si muove* ('But nevertheless it does move'), is also in danger of being regarded as a fiction. G. was sentenced to an indefinite term of imprisonment in the Inquisition, which was soon commuted by Pope Urban, at the request of Ferdinand the Grand Duke of Tuscany, into permission to reside at Siena, and finally at Florence, should the prisoner's health require the change. In his retreat at Arcetri, he continued with unflagging ardour his learned researches, even when hearing grew enfeebled and sight was extinguished. He died on the 8th of January 1642, at the age of 78, and was interred

by ducal orders in the cathedral of Santa Croce, where a majestic monument symbolises his great achievements. His disposition was truly genial; he enjoyed with keenness the social wit and banter of his chosen friends, and the generous pleasures of the banquet; and the readiness with which he offered or accepted atonement, modified a somewhat irascible disposition. The great deficiencies in his character were a want of tact to keep out of difficulties, and a want of moral courage to defend himself when involved in them. His biting satirical turn, more than his physical discoveries, was the cause of his misfortunes. The dignitaries of the church who persecuted G., warned him beforehand in the friendliest way to be 'more prudent.' Their conduct in persecuting opinion, or rather, in G.'s case, *demonstrated fact*, is of course utterly inexcusable; but that is no reason why we should run to the other extreme, and declare G. to be a martyr. No great man had ever less claim to the title. It is also right to add, that the congregation of the Inquisition by which G. was condemned, is not believed by Roman Catholics to speak with the plenary authority of the Catholic Church, nor are its decisions regarded as infallible even by the most extreme ultramontanes. G. was of small stature, but of a robust and healthy frame; his countenance was attractive, and his conversation cheerful. He loved art, and cultivated especially music and poetry. Ariosto he knew almost by heart, and appreciated keenly the beauties of this great classic. Tasso, on the other hand, he unduly depreciated, and inflicted much pain on the sensitive spirit of the poet by his severe criticism entitled *Considerazioni al Tasso*. His own style is nervous, flowing, and elegant. His collected works have been published in 13 volumes, 8vo (Milan, 1811), and at various other places. His devoted pupil, Viviani, has written a life of G.; see also Drinkwater in the *Library of Useful Knowledge*; Sir David Brewster in Lardner's *Cabinet Cyclopædia*; and M. Philardète Chasles's *Galileo Galilei: sa Vie, son Procès, et ses Contemporains, d'après les Documents Originaux* (Paris, 1862). We may briefly recapitulate G.'s most important contributions to physical science under the following heads: 1. The relation between space and time in the case of falling bodies, also the 'three laws of motion'; 2. The path of projectiles is a parabola; 3. The isochronism of the pendulum; 4. That air has weight, also partial discovery that suction is owing to the pressure of the atmosphere; 5. The re-invention of Aristotle's theory respecting sound; 6. The invention of the telescope; 7. The discovery of the satellites of Jupiter, phases of Venus, and spots on the sun. For the nature of these discoveries, see PENDULUM, FALLING BODIES, PROJECTILES, &c.

Galingale (*Cyperus longus*):
a, a spikelet; b, a single flower;
c, pistil; d, end of spikelet in
fruit.

GALINGALE, a name often applied to the tubers of *Cyperus longus*, and sometimes to the whole plant. See CYPERUS.

GALIPEA. See ANGOSTURA BARK.

GALIVM. See BEDSTRAW.

GALL. A synonym for bile, the secretion of the Liver (q. v.).

GALL, FRANZ JOSEPH, the founder of phrenology, was born at Tiefenbrunn, near Pforzheim, on the borders of Baden and Württemberg, 9th March 1758. He studied medicine at Vienna, and settling there, became known as a practical physician, and by the publication of his *Philosophisch-Medicinische Untersuchungen über Natur und Kunst im gesunden und kranken Zustande des Menschen* (Vienna, 1791). But he acquired a much more extended reputation by his lectures on the structure and functions of the brain, which he began to deliver in 1796. See PHRENOLOGY. His views were so subversive of received doctrines on the subject of mind, that a spirit of opposition was excited, and the lectures were prohibited in 1802 by the Austrian government. Along with his pupil Dr Spurzheim (q. v.), who became his associate in 1804, G. quitted Vienna in 1805, and during his travels through Germany, Holland, Sweden, and Switzerland, expounded his views in many of the universities and principal cities, where he found many adherents as well as opponents. In 1807, he settled as a physician in Paris, and there began lecturing and writing for the propagation of his opinions. As a foreigner teaching science to the French, he was discountenanced by Napoleon. On 14th March 1808, he and Spurzheim presented to the Institute of France a Memoir of their discoveries, on which a committee of the members of that body (including Pinel, Portal, and Cuvier) drew up an unfavourable Report. Of this there is a translation in the *Edinburgh Medical and Surgical Journal* for January 1809. G. and Spurzheim thereupon published their *Memoir*, with a reply to the Report, in a volume entitled *Recherches sur le Système Nerveux en général, et sur celui du Cerveau en particulier; suivies d'Observations sur le Rapport, &c.* (Paris, 1809, 4to). This was followed by their larger work, *Anatomie et Physiologie du Système Nerveux, &c.* (Paris, 1810—1819, 4 vols. 4to), with an Atlas of 100 plates; but the two phrenologists having parted in 1813, the name of G. alone is prefixed to vols. 3 and 4; and it alone is borne by a reprint of the physiological portion of the work, entitled *Sur les Fonctions du Cerveau, et sur celles de chacune de ses Parties* (Paris, 1825, 6 vols. 8vo). Of the contents of that edition, there is a summary in the *Phrenological Journal*, x. 459. A German translation of it, entitled *Vollständige Geisteskunde, &c.*, appeared at Nuremberg in 1833; and an indifferent English version by Dr Winslow Lewis, junior, at Boston, United States, in 1835 (6 vols. 12mo). A translation of the chapters *On the Functions of the Cerebellum* is included in a volume with that title, published by G. Combe (Edin. 1838, 8vo). In answer to accusations of materialism and fatalism brought against his system, G. had early published a part of the work under the title of *Des Dispositions innées de l'Âme et de l'Esprit, &c.* (Paris, 1812). He continued to practise medicine and pursue his researches at Montrouge, near Paris, till his death, 22d August 1828. A catalogue of his collection of skulls, &c., is printed in the *Phrenological Journal*, vol. vi. and vii. As a thinker, he was original and independent; as an observer, industrious and persevering; as a writer and lecturer, forcible and clear. Even those who reject his system as insufficiently borne out by facts, allow that he has conferred signal service on science by his discoveries in the anatomy and physiology of the brain, and that by stirring to the bottom many questions regarding mind, and the organic

conditions by which its phenomena are affected, he has contributed to deepen the foundations of psychology, and to render it applicable to human affairs. It is long since the apprehension of danger to religion and morality from his doctrines died away among the intelligent and well informed. In Great Britain, phrenology became known less through G.'s writings than through those of Spurzheim, who came over to England in 1814. So early, however, as 1803 it had been criticised in the *Edinburgh Review*, ii 147. See further, *Transactions of the Phrenological Society*, p. 1 (Edin. 1824); *Phrenological Journal*, vols. 5, 8, 9, 11, 15, 16, 17, and 19; a *Historical Notice of the Discovery of the Anatomy of the Brain*, appended to G. Combe's *Phrenology Applied to Painting and Sculpture*, p. 151 (Lond. 1855); Professor Laycock on *Mind and Brain*, ii 164, 168 (Edin. 1860).

GALL, St, one of the most important manufacturing towns of Switzerland, capital of the canton of the same name, is pleasantly situated on the left bank of the Steinach, at an elevation of 2081 feet above sea-level, and is distant 40 miles from Zürich in a straight line east-north-east. It is a well-built town, surrounded by old walls; but the ditch has been filled up and converted into garden-grounds. Among the principal buildings are the Abbey Church, which was completely modernised in the course of last century; the monastery, portions of which are now occupied by public government offices, and by the convent library, containing 1506 MSS., and among them several of the classics, that were at one time thought to have been lost. See GALL, ST, ABBEY OF. The greatest building is the schoolhouse, which contains a natural history museum and the town library. The manufactures of St G. consist chiefly of cotton goods, particularly of *Swiss muslins*. It has also linen manufactures, carries on bleaching and embroidery extensively, and is the great mart for the produce of Appenzell and Thurgau. Pop. 12,000.

GALL, St (Ger. *St Gallen*), ABBEY OF, a celebrated Swiss Benedictine monastery, which gives its name to the canton in which it is situated. It was founded early in the 7th c. by St Gall, or Gallus, an Irish monk, a disciple of Columbanus, and one of that distinguished band, who in that age, from the various monasteries of Ireland and the kindred establishment of Iona, carried the elements of learning and civilisation over a large portion of the continent of Europe. Gallus had accompanied Columbanus to Anegray and Luxeuil, and ultimately himself, in company with a few followers, repaired to Switzerland, where, in a hermitage on the banks of the Steinach, he acquired such fame for sanctity by his teaching and example, that on his death, there arose, in honour of his memory, what, in progress of time, became one of the most celebrated of the many magnificent establishments of the Benedictine order. The succession of abbots from the days of Gallus is carefully chronicled, and the share which each of them had in the erection and enlargement of the monastic buildings. It will be enough to say that, through the piety and munificence of the faithful, the abbey of St G. gradually became one of the master-pieces of medieval architecture; and that the genius and skill which were lavished on its construction, and on the decoration of its halls and cloisters, had a large share in developing the Christian art of the period. The monks of St G., too, may be reckoned among the best friends and preservers of ancient literature. They were indefatigable in the collection and transcription of MSS.—biblical, patristic, sacred and profane history, classical, liturgical, and

legendary. Some of the MSS. which are still shewn in the library are monuments of the skill and industry of the copyists; and several of the classics, especially Quintilian, Silius Italicus, and Ammianus Marcellinus, have been preserved solely through the MSS. of St Gall. For a time, the abbey was subject to the Bishop of Constance, and an animated dispute was for a long time maintained between that prelate and the monks as to the right of electing the abbot. It ended, however, in the recognition of the right of free election; and ultimately, from the growth of the monastic possessions, and the important position which the abbot held, the monastic domain, which comprised a great part of Northern Switzerland, became a distinct jurisdiction, within which the abbot, like many of his brethren in the great Benedictine monasteries, exercised all the rights of a suzerain. For several centuries, the abbey of St G. held one of the highest places in the order. Its schools enjoyed wide reputation. Its members held a distinguished place among the scholars of medieval Germany; and many of them, as, for example, Notker, are known to have cultivated not only the ordinary learning of the schools, but also physic, mathematics, and astronomy. The school of St G., too, was one of the most eminent for the cultivation of music, and its MSS., preserved in its library, have been extensively made use of by the restorers of ancient ecclesiastical music. A town of considerable importance grew up around the monastery, and was called by the same name; and as the wealth and influence which attached to the dignity of the abbot began to make it an object of ambition to the rich and powerful families, we find the succession of abbots, in the 13th and 14th centuries, sadly degenerated from their pious and learned predecessors in the office. A stringent reform was enforced about the time of the council of Constance; but the burghers of St G. had grown dissatisfied under this rule; and on the outbreak of the Reformation in 1525, they threw off their subjection, and embraced the new doctrines. At the close, however, of the religious war in 1532, the Catholic religion was re-established, and the abbot reinstated, though with diminished authority, in his ancient dignity. At the French Revolution, the abbey of St G. was secularised (1798), and its revenues were soon afterwards sequestered (1805). By a later ecclesiastical arrangement, the abbey of St G. was raised to the dignity of a bishopric, which, in 1823, was united to that of Chur. They were afterwards, however, separated; and in 1847, St Gallen was erected into a bishopric, with a distinct jurisdiction.

GALL, St, CANTON OF, a Swiss canton, bounded on the N. by Thurgau and the Lake of Constance, E. by the Vorarlberg, S. by the Grisons and Glarus, and W. by Zürich and Schwytz. The country is for the most part mountainous; the general slope of the surface being towards the north and north-west. Several of the summits attain a height of 6000 or 7000 feet, one (the Gallanda) a height of 8800, and one (Schirbel) that of 9000. The Rhine touches the canton of St G. near Pfeffers, and for about 50 miles forms its eastern boundary. The chief rivers that intersect the canton are the Seer, the Tamina, and the Thur. Portions of the Lakes of Constance, Zürich, and Wallenstadt, lie within its boundaries. The chief produce of the canton consists of fruit, especially apples and cherries, wine, *kirschwasser*, corn, maize, and potatoes. The amount of corn produced is but trifling, and a considerable part of the land is devoted to pasture. Iron is found in considerable abundance, and of good quality, at Gunzenberg; and coal, as also peat, is raised within the canton.

The manufactures are of linen, muslin, cotton, lace, embroidery, and glass; and wax-bleaching and tanning are also extensively carried on. The linen-trade is of very old standing. Its seat is the town of St Gall, which was celebrated for its linens as early as the 13th c., but it has in later times been almost entirely replaced by the manufacture of cotton.

The erection of St G. into a distinct canton is comparatively of recent date. It was formed upon the secularisation of the domain of the abbot by the union of the abbey territory with several districts previously subject to the older cantons—viz., the Rheintal, Sargans, Werdenberg, Sax, Gaster, Uznach, together with the town of Rapperschwyl; so that the new canton of St G. actually encloses upon all sides the canton of Appenzell, which forms, as it were, an island within the new district. The language is a Swabian dialect of German. The canton of St G. sends eight members to the National Council. Its government is one of the most democratic in Switzerland. It consists of a Great Council, the members of which are chosen for two years by the votes of all citizens above 21 years; and who appoint from among themselves for four years an executive, called the Lesser Council, consisting of seven members. The local prefects and other district officers are elected annually in their several districts. The area of the canton is 772 square miles. Pop. (1860) 181,091, of whom 111,087 were Catholics, and the rest chiefly Calvinists. Chief town, St Gall (q. v.).

GALLA OX, or SANGA, a remarkable species or variety of ox inhabiting Abyssinia. The chief peculiarity is the extraordinary size of the horns, which rise from the forehead with an outward, and then an inward curve, producing a very perfect figure of a lyre, and finally curve a little outwards

figures the animal so as rather to confirm it. The G. O., however, differs from the common ox in having a hump on the shoulders, in the abrupt descent of the back towards the tail, in the greater length of the legs, and in the narrower space between the horns.

GALLAND, ANTOINE, a French orientalist and numismatist, was born in 1646 at Rollot near Montdidier, in Picardy. In 1670 he accompanied the French ambassador, Nointel, to Constantinople, when he visited Jerusalem and other places. He returned to France in 1675, but subsequently made two voyages to the East. Colbert and Louvois interested themselves on his behalf, and procured him the means of devoting himself to study. In 1701, he was made a member of the Académie des Inscriptions, and in 1709, professor of Arabic in the Collège de France. He died 17th February 1715. The greatest part of G.'s writings relate to Numismatics and the East, but the thing which has secured him the most imperishable reputation, is his translation of the *Arabian Nights* in 12 vols. (*Mille et Une Nuits, Contes Arabes*, Paris, 1704—1708). This was the first translation of these grotesque and gorgeous stories ever made into any language of Christendom, and for a good while G. got the credit of being himself the author as well as the translator. Among his other writings, we may mention *Paroles remarquables, bons Mots, et Maximes des Orientaux* (Paris, 1694), and *Les Contes et Fables Indiennes de Bidpai et de Lokman* (2 vols., Paris, 1724).

GALLAS ('invaders'), a race inhabiting the south and east of Abyssinia. The general name by which the tribes designate themselves is *Oroma* (*orma*, men). Although generally belonging to the negro race, they are not purely negroes, but form with the Fulahs, Mandingoes, and Nubas, as it were, the transition to the Semitic variety, and seem to belong to that great family inhabiting the east of Africa, from the frontiers of the Cape land to Abyssinia, and usually denominated the *Kafirs*. They are a vigorous, well-formed people, of a dark-brown colour, with hair frizzled, but not quite woolly, round faces, and small sharp eyes, and are distinguished not less by their energy and warlike spirit, than by their mental capacities. They first appear in history in the 16th c., as a barbarous people, extending their conquests from the interior of Africa, laying waste, by constant incursions, the countries of Eastern Africa, to the mountains of Abyssinia, gradually subduing or expelling the original inhabitants (hence their name), occupying great part of Abyssinia, and advancing as far as the Red Sea and the Gulf of Aden. It is only of late years that their power in Abyssinia, and their incursions into that country, have been partially checked, chiefly by the vigorous government of the king of Shoa, who has subdued some of the G. tribes, and induced them to profess such Christianity as exists in Abyssinia. They still, however, occupy many districts of Abyssinia, and extend their power to an indefinite extent over the countries situated south and south-west of it. Politically, the G. do not form a single nation, but are divided into numerous tribes, forming separate kingdoms and states, which are frequently at war with each other. Most of the G. follow pastoral avocations. Some, however, through intercourse with the semi-Christian, semi-civilised Abyssinians, have become tillers of the soil. The wandering G. are mainly engaged in hunting and the slave-trade. The larger number of the G. are still heathens, though Mohammedanism has lately made great progress among them. Their religion bears a resemblance to that of the *Kafirs*.—Compare

Galla Ox (copied from Vasey's work on *The Ox*).

at the tip, to which they taper gradually. In a specimen presented by Mr Salt to the Museum of the College of Surgeons in London, the length of each horn measured round the outer side is three feet ten and a half inches, the circumference of each at the base is one foot three inches, the distance between the tips three feet four inches. A space of about three or four inches between the horns is occupied by a tuft of hair. Bruce represents the enormous growth of the horns as a kind of disease or monstrosity, accompanied with emaciation of the animal. Salt controverts this account, but

Jomard, *Notices sur les Gallas* (Paris, 1839); Beke, *On the Origin of the Gallas* (London, 1848).

GALLATIN, ALBERT, an eminent financier and diplomatist, was born 29th January 1761, at Geneva, and educated at the university of that city. In 1780 he emigrated to the United States; and was for a short time teacher of French in Harvard College at Cambridge, Massachusetts. In 1786 he settled in the western part of Pennsylvania, and was a representative from that state in the Federal Congress from 1795 to 1801. He soon became one of the ablest debaters in that body, and was for several years the recognised leader of the Republican party. He took an active part in almost every question before Congress, and was especially distinguished for his ready and profound knowledge of political economy and finance. The first formation of the 'Committee of Ways and Means' was due to his suggestion. In 1801, President Jefferson appointed G. secretary of the Treasury, which office he filled with eminent ability during a period of twelve years. He had an important share in the negotiations for peace with England in 1814, and signed, with Adams, Clay, and the other commissioners, the treaty concluded at Ghent on the 14th of December of that year. From 1816 to 1823, G. was minister resident of the United States at Paris. In 1826, he was sent to England as ambassador extraordinary, for the purpose of settling the disputed boundary between the United States and the British possessions, and other important questions. On his return from Europe in 1827, he retired from public employment, and became a resident of New York city. In 1843, he was elected president of the New York Historical Society, which position he held till his death. He was one of the founders, and the first president of the American Ethnological Society. He was the author of a number of valuable publications on the currency and other subjects. He made the languages and characteristics of the native tribes of North America a subject of profound study, and published several papers on this department of ethnology. G. died 12th of August 1849, in his 89th year.

GALL-BLADDER. See **LIVER**.

GALLE'GO, one of the principal affluents of the Ebro, rises at the southern base of the Pyrenees in the province of Huesca, flows south, and after a course of about 90 miles, joins the Ebro a mile below Zaragoza.

G'ALLEON (augmentative of *Galley*), a name formerly applied to ships-of-war of three or four gun-decks, but subsequently transferred to the large merchant-vessels which every year brought to Spain the gold, silver, and other wealth contributed by its Mexican and South American colonies. They were armed, but being heavy unmanageable vessels, and of immense value, were eagerly sought after as prizes whenever a war broke out.

GALLERY, in a *military* sense, is a covered passage, cut through the earth or masonry in a fortification, either as a means of communication, or as a position whence a musketry-fire can be maintained through loopholes. For the latter purpose, galleries are formed occasionally in the counterscarps of dry ditches, where their defenders exercise a flanking fire upon the ditch. With regard to listening galleries, see **MINES, MILITARY**.

In a *naval* signification, a gallery is a sort of balcony projecting from the stern and stern-quarters of large ships. As an adjunct to the principal cabins, galleries form an agreeable resort during fine weather. Under the article **DAUNT**, the gallery of a man-of-war is shewn.

GALLERY, a word with several applications in architecture. A long passage or corridor is called a gallery. A long room, such as is frequently used for exhibiting pictures—a raised floor in any apartment, supported on pillars—a long passage in the thickness of the wall, or supported on cantilevers (as the Whispering Gallery of St Paul's): all these are called galleries. They were of very frequent use in the buildings of the middle ages. The Roodloft (q. v.) is a gallery running across a church at the entrance to the choir, and supporting a large cross. Organ galleries are also frequent, either in the position of the roodloft, or at one end of the nave or transept, or corbelled out from the side-wall.

In old baronial halls, the end next the door was usually screened off for the domestics, and above the screen was almost invariably a gallery for musicians.

In the older German and French churches, the side-aisles were divided into two stories—the upper forming a gallery said to be for the exclusive use of the women.

The arrangement of galleries in tiers one over the other, now so much used in churches, theatres, &c., is entirely modern, dating from the 17th century.

GALLEY, a long, low-built, narrow ship with one deck, much used in the Mediterranean prior to the introduction of steam, and still extant there. Gallies are propelled by sails and numerous oars, the latter being usually worked by convicts or galley-slaves, who are chained to them. The largest vessels of this class were those of the Venetians, some reaching a length of 162 feet, and carrying 12 guns: of these, *half-galleys* and *quarter-galleys* were diminutives. From their small elevation above the sea and swift movement, they were formidable enemies, even to much larger vessels, when smooth water gave play to their evolutions. During the great French war, numberless galleys, fitted as gun-boats, were ready to issue from the Mediterranean ports of Spain and France whenever a British ship was becalmed or disabled near the shore. The celebrated Algerine corsairs committed most of their piracies in swift galleys, which were commonly rowed by the forced labour of Christian slaves.

On board an English ship, the *galley* is the place where the cooking is carried on for the whole ship's company; it is on one of the lower decks, in the fore-part of the vessel.

Galley is likewise applied to some of the boats of a ship-of-war; the captain's galley being usually a swift and elegant boat propelled by six alternate oars.

GALLEY, in Heraldry. See **LYMPHAD**.

GALLEY HALFPENCE. These were coins of Genoa, brought into England by the galley-men, or men that came up in the galleys with wine or merchandise, and thence called galley halfpence. They were broader than the English halfpenny, but not so thick, and probably base metal, because, by 11 Hen. IV. c. 5, and 13 Hen. IV. c. 6, galley halfpence were prohibited as a legal tender. The galleys unloaded at the east end of Lower Thames Street, thence called Galley Quay, where, in the 17th c., were struck tradesmen's tokens, thereof called Galley Quay halfpence (Timbs).

GALLEY-SLAVE. See **BAGNES**.

GALL-FLY (*Cynips*), a Linnean genus of insects, now forming the family *Gallicolæ* (Lat. gall-inhabiting) of entomologists, and belonging to the order *Hymenoptera* (q. v.), section *Terebrantia* (Lat. boring), which section is characterised by the females being furnished with an *ovipositor*. Gall-flies are nearly allied to ichneumons, but principally

differ from them in depositing their eggs not in the bodies of the larvæ of other insects, nor in their nests, but in plants, on the juices of which their larvæ are nourished. The ovipositor of the female is long, slender, in part spirally rolled up when not in use, and lodged in a groove on the under-side of the abdomen, near the origin of which it is attached; it has at its extremity lateral teeth forming a kind of saw. By means of this organ, the insect makes

Bedeguar gall of Wild Rose.

a minute puncture where she is to deposit her egg, which is sometimes in a leaf, and then generally in one of the ribs of the leaf, sometimes in a young shoot or twig, sometimes in a bud, or in some other part of a plant, not excepting the roots; each species of gall-fly choosing some particular plant, and some particular part of the plant, to which it confines its attacks. An irritant fluid is supposed to be lodged in the puncture along with the minute egg, as a tumour immediately begins to form, becoming an excrescence known as a *gall*. The egg itself increases

Various kinds of Galls:

a, oak-apple gall; b, b, berry-shaped galls on oak leaf; c, currant galls; d, gall-fly, magnified.

in size before it is hatched; the gall very rapidly attains its full dimensions; and within it the larva of the gall-fly feeds on the juices of the plant in their most concentrated form; for galls are found to contain the peculiar principles of the plants on which they grow in greater abundance than the adjoining or other parts. It is not until the larva has undergone its transformations, first into the pupa, and then into the perfect insect, that it eats its way out of the gall in which it has previously existed. See *GALLIA*.

GALLIARD (from the French *gaillard*, and that

again from *gai*, sprightly) is the name of a lively dance, the same, according to Brossard, as the *Romanesca*, a favourite dance with the Italians. The air is mostly in $\frac{3}{4}$ or $\frac{2}{4}$ time, but sometimes also in $\frac{4}{4}$ or $\frac{3}{8}$ time. The tempo is also quick and lively, with a flowing melody. A writer in *Notes and Queries* (vol. vii. pages 216, 217) says that he knows at least a hundred different galliard tunes, which are distinguished by different names, probably to indicate with whom they were favourites, such as *The King of Denmark's Galliard*; *The Earl of Essex's Galliard*; &c.

GALLIC ACID ($C_{12}H_6O_6, 2H_2O$) occurs in the form of colourless silky needles which lose their water of crystallisation at 212°; they dissolve slightly in cold water, but require only three parts of boiling water for their solution, and they are freely soluble in alcohol. Solutions of gallic acid have an acid reaction and a sour astringent taste; with the persalts of iron they yield a deep blue colour, and no apparent reaction occurs when they are mixed with a solution of gelatine. The gallates of the alkalis, especially if an excess of the base be present, speedily absorb oxygen, and become brown when exposed to the air; and hence they may be usefully employed in Eudiometry. Gallic acid possesses the property of reducing the salts of gold and silver, and it is on this account that it has been employed in photography.

Gallic acid exists ready formed in small quantity in gall-nuts, in valonia (the acorn-cup of *Quercus agrifolia*), in divi-divi (the pod of *Cassipouira coriaria*), in sumach, and other vegetables. It is formed in association with glycoside from Gallotannic Acid (q. v.), when the latter is boiled with dilute sulphuric or hydrochloric acid; it is likewise produced by boiling a solution of gallotannic acid with caustic alkalis, or (more slowly) by simply exposing a solution of gall-nuts to the air, the process of oxygenation being apparently favoured by the presence of a ferment contained in the gall-nut.

To obtain gallic acid, we mix powdered gall-nuts with water, and expose them freely and for a long time to the air at a temperature of 70° or 80°. The tannin or gallotannic acid becomes gradually converted into gallic acid. We pour away the supernatant brown fluid, and take up the gallic acid from the residue with boiling water, decolorise with animal charcoal, and crystallise.

When gallic acid is exposed to a temperature of from 410° to 420°, it is converted into carbonic acid and *Pyrogallie Acid* (q. v.) ($C_{12}H_6O_8$), which is sublimed, 31 or 32 parts of the latter acid being yielded by 100 of gallic acid. The reaction is represented by the formula—

If gallic acid is mixed with five times its weight of oil of vitriol, a crimson solution is formed, which, if gradually dropped into water, deposits a red substance, partly in granules and partly in crystals. The crystals are *Rufogallie acid* ($C_{12}H_6O_8, 2H_2O$).

Gallic acid is used in medicine as an astringent. The late Dr Todd regarded it as the best styptic that we possess in all cases of internal hæmorrhage, whether hæmoptysis, hæmatemesia, or hæmaturia. The symptoms of Bright's disease of the kidney have also been much alleviated by its use. It may be given in doses of from three to ten grains three or four times a day. As a topical agent in arresting hæmorrhage from external wounds, it is greatly inferior to tannin.

GALLICAN CHURCH, the Church of France, less, however, considered under the relation of

geographical boundaries than in its constitution and principles of church government. The Christian faith was widely diffused in France, even during the lifetime of the apostles; and it especially flourished among the descendants of the Greek colonies of the south, and in the numerous towns and cities upon the Rhone and its confluent rivers. In the persecutions to which the early professors of Christianity were subjected, the Christians of these churches had their full share; and one of the most touching monuments of early Christian literature, is the letter of the Christians of Lyon and Vienne to their brethren in Asia, on the martyrs of these churches, which Eusebius has preserved in his *Ecclesiastical History* (book v. c. 1). Although sharing in the general literary inferiority to their eastern brethren which characterises Western ecclesiastics during the early period, the church of Gaul numbers several eminent names in the literature of the 3d, 4th, and 5th centuries. The works of Irenæus, Bishop of Lyon, are among the most important for the history of doctrine of all the early patristic remains; and in the following century, Sulpicius Severus, Hilary of Poitiers, Hilary of Arles, Vincent of Lerins, Prosper, Victor, Eucherius, Salvian, and other writers, combine to form a body of literature of which the later modern representatives of the French Church are not unreasonably proud. The hierarchical organisation, also, of the church of Gaul was, at a very early period, among the most complete and regular throughout the churches of western Christendom; and in the council held at Arles in 314, we even recognise the titles of many bishops of sees which are still represented in the catalogue of the French episcopacy.

But the history of the G. C., so far as regards the development of those peculiar principles which have acquired a distinctive name and status in Roman Catholic theology, begins at a much later period. We shall see elsewhere the origin and progress of the temporal power of the papacy. See PAPACY. It will be enough, in this place, to observe, that, from circumstances which are differently viewed by the opposite schools of theology, the Roman pontiffs began, from the very date of the establishment of the Western Empire, to exercise a large and widely extended influence over the civil as well as ecclesiastical affairs of the several European kingdoms. On the other hand, owing to the intimate connection between the church and state in most of these kingdoms, and especially to the feudal relations between the crown and the church dignitaries, most of whom held the temporalities of their benefices under the crown by the ordinary feudatory tenure, the crown also asserted a correlative claim to certain privileges in respect of ecclesiastical affairs. The satisfactory adjustment of these conflicting claims was the great problem of medieval polity; and the alternations of the struggle between them form the staple of medieval history. More than one of the French sovereigns engaged in a conflict with the Roman see as to the respective authority of the two powers; these conflicts naturally called out a division of opinion among the members of the church of France, one party supporting the papal claims, and the other maintaining the adverse prerogatives of the French crown, and the privileges of the national church of France. The latter party, professing to represent the rights of the G. C., have given a name to the principles which they profess; and the appellation of Gallicanism has come to designate, in general, that system in Roman Catholic theology which, while it recognises the primacy of the Roman pontiff, by divine right, over the universal church, yet asserts the independence of national churches in many details of self-govern-

ment and of local discipline, and limits the exercise of the papal prerogatives by canons and decrees of general councils and by the laws of the universal church. It must be added that, while the Gallican theory to this extent claims an exemption from dependence upon the authority of the Roman pontiff, it acquiesces, on the other hand, to an almost proportionate degree, in the assumption of ecclesiastical authority on the part of the state. Gallicanism, in truth, in many of its details, falls into the grossest form of Erastianism.

We can recognise the working of these principles in the opposition which the so-called Isidorian Decretals (see ISIDORIAN DECRETALS, HINCMAR OF RHEIMS) encountered in France; and although the body of the clergy stood aloof, they were carried to their most extreme extent by Philippe the Handsome in his contest with Boniface VIII. The conflicting claims of the rival popes in the Western Schism (see WESTERN SCHISM) tended still more to weaken the papal authority; and the expedient which was then adopted for the extinction of the schism—viz., that of convening a general council to pronounce upon the respective claims of the pretenders to the papacy, gave prominence and significance to what has since been regarded as one of the leading dogmas of Gallicanism—the superiority in point of authority of a general council to the pope. The details, too, of the disciplinary enactments of the councils of Constance and Basle, which were drawn up in this spirit, were mainly directed towards the limitation of the papal authority in the exercise of church patronage within the limits of the national church; and these enactments were in the main embodied into the French law by the celebrated Pragmatic Sanction of 1438. See PRAGMATIC SANCTION.

The Pragmatic Sanction was superseded in 1512 by the concordat of Leo X. with Francis I. The large share in the dispensation of church patronage which the French crown enjoyed under that concordat had the effect of still further nationalising the French Church, and increasing the jealousy of the crown as to the papal interference. The great jurists, Pithou and Duping, in asserting the liberties of the church, equally enforced the privileges of the crown. In the development of the absolutism of the monarchy, which reached its height under Louis XIV., the ecclesiastical prerogative of the crown was enlarged as much as its political authority; and a contest which arose between this monarch and Innocent XI., on the right of the crown to the so-called *Droit de Regale* (see REGALIA), led to the well-known declaration of the French clergy in 1682, which has since been regarded as the charter of Gallicanism. This formulary emanated from an assembly of the French clergy, held by royal authority in 1682, at which the celebrated Bossuet was present. It consists of four articles. The first declares that 'the jurisdiction of St Peter and his successors in the Roman see as vicars of Christ on earth, although divinely bestowed, is confined to things spiritual and appertaining to salvation, and does not extend to civil or temporal affairs.' The article therefore declares 'that princes are not subject in temporal things to any ecclesiastical authority;' that they cannot be deposed 'either directly or indirectly by the power of the keys, and that their subjects cannot be dispensed from their subjection or released from their allegiance.' The second article renews the declaration of the council of Constance with regard to the superiority of a general council over the pope, and declares that that article is not to be restricted in its application to a period of schism such as existed at the time of the council. The third asserts that the authority of the pope is 'to be restricted by the

canons of the universal church,' and that 'the rules, customs, and institutions of the Gallican kingdom and church remain in full force.' This is the article which asserts the celebrated 'Gallican Liberties.' The fourth article, while it concedes to the pope 'the chief part in questions of faith,' and professes that 'his decrees extend to each and every church,' nevertheless maintains 'that his judgment is not irreformable, unless it shall have been confirmed by the consent of the entire church.' The chief rules, customs, and institutions of the G. C. referred to in the third article are, that the G. C. does not receive all the decrees of councils and of popes in matters of discipline, and that those only are in force which are so received; that the G. C. holds itself free to receive or reject the rules of the Roman chancery; that the Roman pontiff cannot levy any impost from the French clergy without their own consent; that he cannot bestow of his own motion on a foreigner any benefice within the French Church; that neither he nor his legates can hear French causes in 'the first instance,' and that even in cases of appeal he is bound to assign native judges to hear the appeal, even when the appellant should be a metropolitan or primate; that the French bishops shall not be required to attend any general council unless with the permission of the crown. The last of these 'customs,' as also those which make the receiving or not receiving the general canons of discipline optional in France, and which practically throw the decision into the hands of the civil power, have been with much show of reason denominated the 'Slaveries' rather than the 'Liberties' of the Gallican Church.

This 'Declaration' was strenuously enforced by Louis XIV. It was imposed upon the universities and all public ecclesiastical bodies, and its acceptance was made a condition of appointment to offices in the church; but it was in the same proportion distasteful to the popes. It was condemned by Alexander VIII. in 1690, by Clement XI. in 1706, and again by Pius VI. in 1794; but both the acceptance of the articles by the French clergy, and the condemnation of them by the Roman pontiffs, are understood to be with certain reservations as to the particular doctrines. Within the present century, and especially since the late collision between the civil and ecclesiastical authority, the opinions of the French clergy have undergone a decided change. The Gallican doctrines are now much less commonly held, and in a less extreme form. The same doctrines were also adopted in other national churches, and especially in the ecclesiastical principalities of Germany (see FEBRONIANISM), and in the German empire under Joseph II. Here, also, they have fallen into discredit with the church party.

The G. C. underwent very extensive modifications at the close of the 18th and the beginning of the present century, not merely by the enactment of what was called the 'civil constitution of the clergy,' and which introduced into the constitution of the church a large infusion of the presbyterian, and even the democratic element, but by the concordat of Pius VII. with Bonaparte as First Consul, which reduced the number of sees, brought the ecclesiastical divisions of the country into harmony with its new political distribution into departments, diminished the number of festivals, and confirmed the suppression of the ancient religious establishments, and the confiscation of the church property throughout France. Under the present emperor, the Church of France has recovered somewhat of her old external prestige. Compare De Maistre's *De l'Eglise Gallicane*; Dupin, *Les Libertés de l'Eglise Gallicane* (Paris, 1824); and Frayssinous, *Les Vrais Principes de l'Eglise Gallicane*.

GALLIENUS, PUBLIUS LICINIUS, a Roman emperor from the year 259 A.D.—when his father Valerian, who had made him co-regent with himself, was taken prisoner by the Persians—to 268 A.D. His authority was limited almost entirely to Italy, for throughout the provinces the legions for the most part revolted, and raised their commanders to the dignity of Cæsars. Hence the period is known in history as the Time of the Thirty Tyrants. In the East, the honour of the Roman arms was maintained by Aurelian, Probus, and others, who found a useful ally in Odenathus, ruler of Palmyra, and his wife Zenobia (q. v.), to whom G. intrusted the care of the war against the Persians. In the West, however, dangers thickened about him. Aureolus was proclaimed emperor by the legions of Illyricum, and having marched into Italy, seized Milan, and proceeded towards Rome. The war between the two was carried on for some time with undecided success, but G., while besieging his adversary in Mediolanum (Milan), was murdered by some of his officers, 268 A.D. He was succeeded by Claudius II.

GALLINACEOUS BIRDS (Lat. *gallus*, a cock), or RASORES (Lat. scrapers), an order of birds, more generally valuable to man than any other order, containing at once the most important species domesticated as poultry, and those most sought after as game. The common Domestic Fowl may be regarded as the type of the order. Like it, the gallinaceous birds in general have a small head; a rather short bill, with the upper mandible a little arched; nostrils placed on the sides of the bill, and usually in a soft membranous space at its base; the figure bulky; the wings short, and not governed by powerful muscles, nor adapted for long or rapid flight; the feet with three toes before, and one behind—which is articulated higher than the others, and is sometimes wanting—adapted for walking on the ground and for scraping, which is much resorted to, in order to procure food and for other purposes; the digestive organs complex, the crop large, the gizzard very muscular, the intestine long, with two very large cæca. The head, at least of the males, is very generally furnished with appendages, as a crest, comb, wattles, &c. The feet of the males are also often furnished with spurs, and at least during the breeding season the males are very quarrelsome. The males of many species are birds of splendid plumage; that of the females is sober, but females of very advanced age often assume a plumage similar to that of the males. Some of the gallinaceous birds are polygamous, some pair at the breeding season; the nest of all of them is artless, and the males take no part in incubation, nor in the rearing of the young. The young are comparatively feathered when hatched, and are immediately able to run about and pick up food for themselves, but are for some time most affectionately tended and protected by their mother, and by her the proper food is sought for them and pointed out to them, or broken into sufficiently small pieces, and laid before them. The gallinaceous birds have unmelodious voices. Except the curassows, they make their nests on the ground. Some of them are found in almost all parts of the world. Besides those already named, guans, pheasants, grouse, partridges, quails, ptarmigans, peacocks, turkeys, guinea-fowls, tragopans, and tinamous, may be mentioned as examples of this order. Pigeons are generally ranked in it by ornithologists, but rather doubtfully, as they differ not a little from the true gallinaceous birds. See COLUMBIDÆ. Interesting analogies have been pointed out between this order of birds and the order of Ruminants among Mammals, in the complexity of the digestive organs, bulkiness of the frame, low intelligence, easy domestication, usefulness to man, and proneness

to variation from the influence of external circumstances, giving rise to different breeds.

GALLINULE (*Gallinula*), a genus of birds of the family *Rallidae*, closely allied to the Coots (q. v.), and having the upper mandible similarly extending on the forehead in a naked soft plate, but the toes furnished with an undivided narrow marginal membrane. This membrane, however, and the great length of the toes, enable the gallinules to swim well, and all of them are aquatic. The species are pretty numerous, some of them confined to tropical regions. One only is found in Britain, the **COMMON G.** (*G. chloropus*), also known as the **WATER-HEN**, or **MOOR-HEN**. It is a very widely diffused species, being found in most parts of the world. The G. is about 13 inches in length, the tail very short; the general colour of the plumage deep olive brown on the upper parts, blackish gray beneath, the ridge of the wing and the under tail-coverts white. The bill is red at the base, and yellowish green at the tip; the legs and toes green. In situations favourable for them, such as artificial ponds, gallinules may often be seen in considerable numbers together, swimming with a peculiar nodding motion of the head. They seek their food both on the surface of the water and by diving, partly also among the grass of meadows and river-banks. A frequent jerking of the tail is very characteristic of them. When alarmed, they sometimes seek safety by flight, but more frequently by hiding among rushes or reeds. They make their nests near the water which they frequent, and usually on the ground among stumps, roots, and reeds; the nest contains from seven to ten eggs. The flesh of the G. is well flavoured.

GALLIOT, a Dutch vessel carrying a main and a mizen mast, and a large gaff-mainsail. Galliot—

Dutch Galliot (from the *Boy's Own Book of Boats*).

strong-built, flat-bottomed ships—of 400 to 500 tons burden, were formerly used also as bomb-vessels.

GALLIPOLI (the *Callipolis* of the Greeks), an important commercial town of Italy, in the Neapolitan province of Terra di Otranto, is beautifully situated on the eastern shore of the Gulf of Taranto, on a steep insulated rock in the sea, connected with the mainland by a fine arched bridge of stone. It has a good harbour, although somewhat difficult of access, owing to the rocks surrounding its entrance, and in time of war is an important position, being strongly protected by fortifications and a castle, as well as by the peculiarity of its site. G. is remarkable for its oil-tanks, excavated in the solid limestone, in which the famous oil of Puglia is deposited for exportation. Pop. 10,653.

It is the see of a bishop. In 1834, the revenue from the oil-trade amounted to 8,187,355 francs. Other interesting features of the place are the ancient fountain, a fine monument of antiquity, and adorned with antique figures in bas-relief; the castle, erected by Charles of Anjou, commanding the port and bridge, and possessing considerable defensive strength; and the cathedral, erected in 1629 by Francesco Biachettini, and containing some fine paintings of Coppola.

It is said that Christianity was introduced here as early as 44 A.D. In 450, the town was sacked by the Vandals; in 1284, it was destroyed and almost depopulated by Charles of Anjou; and during subsequent centuries, suffered severely from the Venetians, French, Spaniards, and Turks. See *Viaggi in Sicilia ed in Gallipoli*, by Baron Riedesel.

GALLIPOLI, PENINSULA OF (the ancient Thracian Chersonesus), a portion of the province of Rumili, in European Turkey, is situated between 40° 3' and 40° 38' N., and separates the strait of Dardanelles on the east from the Gulf of Saros on the west. It extends in a south-west direction, is about 55 miles in length, and varies from 4 to 13 miles in breadth. The principal town on the peninsula is Gallipoli (q. v.).

GALLIPOLI, an important town and seaport of Turkey in Europe, in the province of Rumili, is situated on the peninsula of the same name, at the north-eastern extremity of the strait of the Dardanelles, and is 90 miles south of Adrianople, and about 130 miles west-south-west of Constantinople. It was once fortified, but its only defence now is 'a sorry square castle with an old tower.' G. is poorly and irregularly built, its houses miserable, and its streets dirty, but its bazaars are extensive and well stocked. It is the most important town on the Hellespont, has two ports, and numerous fountains and mosques; and its inhabitants, comprising merchants of all nations, carry on a flourishing trade in corn, wine, oil, &c. Pop. 30,000.

G. is the see of a Greek bishop. In the town and neighbourhood are seen many remains of ancient sculpture and architecture, the most noteworthy of which are the magazine and cellars built by Justinian. The town was taken by the Turks in 1357, and formed the earliest Turkish possession in Europe.

GALLIPOT, the name given to a pot painted and glazed, commonly used for medicine. The origin of the name is uncertain, some deriving it from the Dutch *gleye*, clay, or *glei*, glaze, and others from the Spanish *gala*. There seems to be some doubt whether the word 'galley' does not apply to the shape. Glazed coloured tiles, however, were called 'galleytiles.' The earliest mention of gallipots is in Sir T. Howard's Household Book of the year 1465, edited by the Roxburghe Club, *Archæol. Jour.* 1861, p. 138.

GALLIVATS, large row-boats, formerly, and still to some degree, used in eastern waters. They rarely exceed seventy tons, carry two masts with high triangular sails, and are generally armed with a few small swivel guns, fastened on the bulwarks. The Malay pirates employ these swift but somewhat fragile vessels.

GALLOMA'NIA. See **ANGLOMANIA**.

GALLON, the standard measure for liquids and dry goods throughout the United Kingdom. It has existed as a measure from the earliest times, and in consequence, has undergone many changes. In the time of Henry III., it was enacted that the gallon should be 8 lbs. of 12 ounces each, an ounce being

the weight of 640 dry grains of wheat from the middle of the ear.

In 1650, there were three distinct gallon measures—viz., 1, the gallon measure in common use, which contained about 231 cubic inches; 2, the customary standard at the Guildhall, which, though not a legal standard, was frequently referred to as such, even by the law-officers of the crown; and though generally estimated at 231 cubic inches, in reality contained only 224; 3, there was also the legal standard measure, preserved at the Treasury, which contained 282 cubic inches.

Besides these three, there was another gallon measure frequently employed for measuring corn, called the Winchester gallon. This measure, though directed in William III.'s reign to contain 269 cubic inches, was soon afterwards changed to 272½ cubic inches, at which value it remained for a long period.

In 1706, the gallon of 231 cubic inches was made the standard wine gallon.

These measures were gradually changed in value, and appropriated to the measurement of particular substances, till, in 1825, just before the passing of the 'Act for Ascertaining and Establishing Uniformity of Weights and Measures,' they stood thus:

In old dry or corn measure, the gallon = 268·6 cubic inches.
In old wine measure, " " = 230·85 " "
In old ale and beer measure, " " = 282 " "

In January 1826, when the above-mentioned act came into operation, all these measures were abolished, and it was enacted that the standard measure of capacity for all liquids and for dry goods not measured by heaping, shall be a gallon containing 10 lbs. av. of distilled water, weighed in air (the barometer being at 30 inches, and the thermometer at 62°).

This gives 277·274 cubic inches for the imperial gallon, and by subdivision or multiplication of this standard, the other measures can easily be found. See WEIGHTS AND MEASURES.

GALLOON, a narrow fabric composed of silk or worsted, or of both. It is usually employed for binding garments, curtains, &c. The small band worn round gentlemen's hats is an example.

GALLOTANNIC ACID ($C_{12}H_{10}O_{14}$) is the most important of the various forms of tannin or tannic acid. It usually occurs as a spongy, light, inodorous, colourless, or faintly yellow mass, which is easily reduced to a fine powder, which possesses a strongly astringent, but not a bitter taste. It is freely soluble in water, the solution reddening litmus paper, and dissolving the carbonates with effervescence. With the persalts of iron, gallotannic acid gives a blackish blue precipitate of gallotannate of iron, and even when the iron solution is extremely dilute, a violet tint is evolved. This gallotannate of iron is the basis of ordinary writing ink (q. v.); and the reaction that we have described is so sensitive, that gallotannic acid is employed in the laboratory as a test for the detection of the persalts of iron. Gallotannic acid likewise precipitates tartar emetic, nearly all the vegetable alkaloids (morphia, quinia, &c.), the albuminates, and gelatine. If a piece of raw hide, freed from hair, be immersed in a solution of gallotannic acid, the gelatigenous tissue and the acid combine, and leather is formed; and if the skin be of sufficient size, all the gallotannic acid is removed from the solution.

Gallotannic acid fuses when exposed to heat, and at a temperature of about 120° it is decomposed, and yields pyrogallie acid ($C_{12}H_6O_6$) and metagallie acid ($C_{12}H_4O_6$), while water and carbonic acid are expelled. When a watery solution of gallotannic acid is excluded from the air, it remains

unchanged; but if the air is allowed free access to it, a fungous or mouldy growth is developed, oxygen is absorbed, carbonic acid is given off, and the gallotannic acid becomes decomposed into Gallic Acid (q. v.) and sugar. The same decomposition is more rapidly induced by the action of dilute sulphuric acid, the reaction being exhibited in the following formula:

On boiling gallotannic acid in a concentrated solution of potash, gallic acid is also formed.

The composition of the salts of this acid is but imperfectly known, but the acid is generally considered as tribasic. None of the salts crystallise, and when in solution or in a moist state, they rapidly absorb oxygen, and become decomposed.

Gallotannic acid occurs in large quantity in the gall-nut, which contains, according to Pelouze, as much as 40 per cent. of this acid, and 3·5 per cent. of gallic acid (Guibourt has found that some nuts contain as much as 65 per cent. of gallotannic acid); it is likewise found in all parts of the gall or dyer's oak (*Quercus infectoria*), in sumach (*Rhus coriaria*), and in green tea.

The best method of obtaining it is from powdered gall-nuts, by extraction with commercial ether (which contains about 10 per cent. of water), in the percolation or displacement apparatus.

Gallotannic acid is employed in medicine, in chemistry, and in the arts. Its uses in medicine are due to its powerful astringent action. It is employed topically as a styptic in wounds, bleeding gums, piles, &c., and internally as an astringent in hæmorrhage from the lungs, stomach, bowels, &c.; as we know that it becomes converted into gallic acid in its passage through the system, it is probably the latter acid which acts on remote parts when gallotannic acid is administered. Internally, it may be given in doses of from three to ten grains, three or four times a day, in pills or in solution. It may be used as an astringent gargle or lotion, in the form of a watery solution containing three or more grains to the ounce. The compound ointment of galls, which is the best topical remedy for piles without hæmorrhage, owes its efficacy to the gallotannic acid contained in the powdered galls.

In chemistry, it is used in solution as a test for gelatine, persalts of iron, &c.; and in the arts, it serves various useful processes, especially in relation to the preparation of leather, and the manufacture of white wines.

GA'LOWAY, the name of an ancient province in the south of Scotland, still employed to designate the counties of Kirkcudbright and Wigton. The extent and early history of G. are alike obscure. By some historians, it has been asserted to have comprehended, in addition to Kirkcudbright and Wigton, Nithsdale, Annandale, Teviotdale, Carrick, Kyle, Cunningham, and Renfrewshire; but the evidence for such assertion is not satisfactory. Gallwegia is mentioned in 1124, in a charter granted by David I. of Scotland to the monks of Selkirk, and at that time its dimensions appear to have been no larger than those the modern application of the name implies. Of the eight tributary princes who are said to have waited upon Edgar king of England at Chester, in 973, one was 'Jacobus rex Galwalliæ.' The name, however, must have come into use after the time of Bede the historian (died 735), for in speaking of the province, which then formed part of the Bernician or Northumbrian kingdom, he makes no mention of it. Its origin is doubtful, but has obvious reference to the Gaelic

people by whom it was possessed. The original inhabitants of the country appear to have been of Celtic origin; they are believed to have formed two distinct tribes, the Selgovæ and Novantes—the former holding the country east of the Dee, along with a portion of Dumfriesshire, while the latter held the portion lying to the west. After the departure of the Romans, in the first half of the 5th c., G. was overrun by the Anglo-Saxons of Northumbria, by whom, however, the native Celtic inhabitants do not appear to have been ever thoroughly subdued. About the 12th c., G. is spoken of by English writers as 'the land of the Picts,' and its inhabitants as 'the Picts.' In Scottish charters, the inhabitants were called simply 'Gallowidenses,' or men of Galloway. G. was now ruled by its own princes and its own laws, the kings of Scotland, however, exercising a nominal sovereignty over it. It was not until the reign of Alexander II. that the power of these great chieftains was completely broken by the crown. The last of them, Alan of Galloway, constable of Scotland, died in 1233, when his great possessions were divided among his three daughters. For the extent, population, natural productions, &c., of G., see KIRKCUDBRIGHTSHIRE and WIGTONSHIRE.

GALLOWAY, MULL OF, a rocky headland, the southern extremity of the peninsula called the Rhins of Galloway, in Wigtonshire, is the most southern point of Scotland. It is $1\frac{1}{2}$ mile long, and $\frac{1}{2}$ of a mile broad. On this headland, in lat. $54^{\circ} 38' N.$, and long. $4^{\circ} 52' W.$, is a light-house, 325 feet above the level of the sea, the light of which is seen at the distance of 21 nautical miles.

GALLOWES, PIT and G. See FOSSA ET FURCA; also, EXECUTION, HANGING.

GALLOWES-BITS, the name applied on board ship to two strong frames of oak, on which the spare topmasts and yards are lashed.

GALLS, or **GALL-NUTS**, are of various shapes, but the oak-galls chiefly used in commerce are nearly globular, with slightly pointed excrescences sparingly placed on their surface. They are remarkable for containing a peculiar acid called *gallic*, which is only an altered condition of tannic acid, and their value is entirely due to the great accumulation of this principle in the diseased condition of the vegetable tissue which constitutes the gall. This gallic acid (q. v.) is easily separated in the form of beautiful white acicular crystals, which, after a little exposure, become pale yellow. It is in extensive demand as a fixing agent for photographic pictures. Until this demand was created, only three or four kinds of galls were known in commerce, and these were almost wholly employed for dyeing purposes, a small quantity of the common Turkish galls being also used medicinally; now, several others are imported in considerable quantities. The following are the chief:

1. The Turkish galls, of two kinds, *blue* and *white*; these are by far the most common in use. They are chiefly imported from Constantinople and Smyrna, from which places the average imports of the last five years have amounted to 300 tons—an enormous quantity, when we consider how they are produced, and the industry necessary to collect so vast a quantity. They are each about the size of a round nutmeg, and the blue, which are the best, are entire, being gathered before the escape of the insect. The so-called white galls are of a yellowish-brown colour, and each is perforated with a small round hole, about the sixteenth of an inch in diameter, whence the insect has escaped. These galls are produced by a species of *Cynips* (*C. quercus-galli*) on the dyer's oak (*Quercus infectoria*), a native of

Asia Minor, from the Bosphorus to Syria, and from the Grecian Archipelago to the frontiers of Persia. Of this kind of gall, several varieties are known in commerce, as the Aleppo galls; the Syrian or Mosul galls, which are the best known; the Tripoli Taraplus or Tarablous galls, obtained from Constantinople; and the Smyrna galls.

2. The small Aleppo or coriander gall, which is generally about the size of a large pea. They are always perforated or empty galls, and are of a brownish-yellow colour, round, and with small blunt spines. The quantity used in this country is not very large.

3. The large Bassorah, Bussorah, or Mecca gall, which are the largest galls known in commerce; they are as large as an Orleans plum, smooth, except a ring of curious slightly raised excrescences sometimes found round the middle, dividing the gall into two hemispheres. They are reddish brown, and are said, when on the trees (*Quercus infectoria*), to be coloured as brightly as apples. These are the apples of Sodom, or the Dead Sea apples, bright to the eye, but filled with a gritty astringent matter, which is likened to ashes; it is formed on the *Quercus infectoria* by *Cynips insana*. These are not extensively imported.

4. The acorn gall, Knopperrn, Knobben, Hungarian, or German gall. This is found chiefly in Hungary, and is much used by the German dyers; it is also occasionally used in this country. It is a curious irregular-shaped brown gall, deeply furrowed, and covered with angular excrescences. It is produced on the common oak (*Quercus pedunculata*) by *Cynips Quercus calycis*.

5. The small East Indian galls called Mahee, and Sumrut-cool-tooia, are obtained from the Indian Tamarisk (*Tamarix Indica*). They are very small, about the size and colour of tares, and are so rough and irregular in form, that they look rather like little lumps of dried garden-soil.

6. The Chinese galls, or Woo-pei-taze. These very curious vegetable excrescences were regarded only as curiosities ten years since, but they now form regular articles of commerce. They are of a very irregular shape, branching out sometimes like fingers. Their length seldom exceeds two inches; they are rarely more than a quarter of an inch in diameter at the base, where they spring from the tree, but they spread out as much sometimes as an inch and a half to two inches. When broken, they are found to consist of a thin shell, not thicker than a walnut-shell, of a dark-yellowish or reddish-brown colour internally, and semi-transparent; but externally they are covered with very fine down, and consequently look like the young horns of a stag when just budding. They are produced on the *Rhus semi-alata* (see SUMACH), by an insect not yet known to science. Since the Japanese ports have been opened to British commerce, considerable imports of these curious galls have been received from that country. They are rather more branched, the branches or lobes being smaller than in the Chinese variety, but in all other respects they are identical.

A very great many galls are known in most parts of the world, and in our own country the oaks yield numerous species, but those above enumerated are the galls of commerce: few others have ever been found to pay the expense of collecting. Galls are extensively used in dyeing, chiefly for the production of black colours, with logwood and the salts of iron, either for dyeing in the piece, or printing patterns; in each case, the material is first submitted to the action of a solution of the galls, and afterwards to another of the dye-wood and iron salt. They are also an important constituent in writing-ink (see

(ink), and are used in tanning the finer kinds of fancy leathers.

GALL-STONE. See CALCULUS, BILIARY.

GALOCHES. See GOLOSSES.

GALT, JOHN, a distinguished Scottish novelist, was born in Irvine, on the 2d May 1779. His father, who was a captain of a ship in the West Indian trade, left Ayrshire in 1780, and fixed his residence in Greenock. In that town, G. received his education, and was then placed in the custom-house. He remained there till 1804, when, panting after literary distinction, he proceeded to London with an epic poem on the battle of Largs in his portmanteau. On reaching the metropolis, he printed his epic, but becoming dissatisfied with its merits, he ultimately withdrew it from the market. After a few years, his health began to fail, and he was obliged to seek relief in a more genial climate. At Gibraltar, he made the acquaintance of Lord Byron—flushed with his first success in the *English Bards and Scotch Reviewers*—and his friend Mr Hobhouse, and the three travellers became fellow-voyagers. Separating from his new friends, G. visited Sicily, then Malta, and finally repaired to Greece, where he again renewed his acquaintance with Byron, and had an interview with Ali Pacha. He then proceeded to Constantinople, and afterwards to the shores of the Black Sea. On one occasion, when detained by quarantine, he sketched six dramas, which were afterwards given to the world. On his return, he published *Letters from the Levant* with considerable success, but first displayed the possession of distinct and individual power in *The Ayrshire Legatees*, which was published in *Blackwood's Magazine* in 1820. *The Annals of the Parish*, a far superior work, appeared the year after, and met with unquestionable success. Having hit on the true vein, he worked it assiduously, and produced *Sir Andrew Wyllie*, *The Entail*, *The Steam-boat*, and *The Provost*, with great rapidity. He then diverged into the walk of historical romance, and published *Ringan Gilhaize*, a tale of the Covenanters; *The Spawwife*, *Rothelan*, and *The Omen*. These works, although full of striking scenes, and abounding in powerful writing, were not so successful as his earlier and less ambitious performances. G., whose hands were always equally full of literary and commercial undertakings, was now busily engaged in the formation of the Canada Company; but before he left England for his distant scene of labour, he gave to the world *The Last of the Lairds*.

He departed for Canada in 1826, but, disappointed in his expectations, he returned to England in the course of a year or two, and recommenced his literary labours with his usual rapidity. In a short time, he published a novel, *Laurie Todd*, which was followed by *Southernman*, a romance of the days of Queen Mary; and this by a *Life of Lord Byron*, which ran through several editions, but which was roughly handled by the critics. In 1834, he published *Literary Miscellanies* in three volumes. He now returned to Scotland, utterly broken in health and spirits; and after suffering several attacks of paralysis, he expired at Greenock on the 11th of April 1839.

G. was a voluminous and unequal writer; but while several of his productions are already forgotten, others of them will perish only with the language. In depicting provincialism, in representing life as it flows on in small towns and villages—communities in which the successful shopkeeper may aspire to be the chief magistrate, and in which the minister is the most important personage—he is without a rival. He has founded a school of writers in Scotland, but as yet his followers

have produced no work equal to *The Provost* or *The Annals of the Parish*.

GALT, a thriving town in the county of Waterloo, Canada West, principally built of stone. It stands on both sides of the Grand River, about 55 miles from its entrance into Lake Erie. The eastern and western parts of the town are connected by two wooden bridges, resting on massive stone piers. The environs of the town are noted for their beauty. The first house of G. was built in 1816, amid a dense forest of pines, which then covered its site. The inhabitants now number about 4000, the majority being of Scotch descent. It contains ten places of public worship, four being Presbyterian, three Methodist, one Episcopal, one Roman Catholic, and one Baptist; the last-named belongs to the coloured population. It supports one grammar and one common school: the average attendance at the latter being about 500; and has an extensive library and public reading-room in connection with a mechanics' institute. Among its industrial establishments are several woollen manufactories and iron foundries. The manufacture of edge-tools is carried on to a large extent. The trade of the town is greatly promoted by the Great Western Railway, a branch of which passes through Galt. The local affairs of G. are managed by a mayor and council of fifteen members.

GALVANI, LUIGI, a famous physician and anatomist, was born at Bologna, 9th September 1737. At an early age, he evinced a strong inclination to devote himself to a monastic life, and his studies in the university of Bologna were, with this view, chiefly directed to scholastic philosophy, rather than to general science. Swayed, however, by the persuasion of his friends, he relinquished his intention of entering the church, and determined to follow the profession of medicine, selecting for special investigation the departments of physiology and comparative anatomy. At this time, he enjoyed the benefit of studying under some of the most eminent medical professors of the day—Beccaria, Tacconi, and Galcazzi, whose talented daughter he subsequently married. So distinguished by his knowledge and ability did he soon become, that in 1762 he was elected professor of anatomy in the institute of his native city, when his lectures, although not remarkable for eloquence, were clear, accurate, and comprehensive, and enjoyed much popularity. His writings are not numerous, but all contain valuable scientific matter, and are characterised by a rare precision and minuteness of details. Two treatises, which added considerably to his reputation, are—*Considerations on the Urinary Organs*, and *On the Organs of Hearing of Birds*. But to a purely casual discovery G. owes the wide celebrity attached to his name. Many versions of this circumstance have obtained credence; but the simple fact seems to be, that G.'s wife, a woman of penetrating intellect, happened one day to witness with surprise the convulsive muscular movements produced in a skinned frog by its inanimate body having been accidentally brought into contact with a scalpel which lay on the table, and had become charged by contact with an adjoining electrical machine. She hastened to communicate the interesting phenomenon to her husband, who at once instituted a prolonged series of experiments. See GALVANISM, and ELECTRICITY, ANIMAL. G. died 4th December 1798. Some time previously, he had lost in his wife a cherished companion, and was deprived of all his public emoluments, in consequence of his refusal to take the oaths prescribed by the Cisalpine Republic, of which Bologna then formed a part. His writings have been chiefly

GALVANISED IRON—GALVANISM.

published in the memoirs of the Bologna Institute of Sciences, including the most remarkable production of his pen, the treatise entitled *De Viribus Electricitatis in Motu Musculari Commentarius*.

GALVANISED IRON. This name is given to plates of iron coated with zinc, without any reference, as its name would imply, to galvanism. Most probably, it was applied by its French inventor for the special purpose of misleading, and for concealing the real nature of the manufacture.

The value of giving a thin coating to iron, of some easily fusible metal much less liable to oxidation than itself, has been long known and acted upon, as in the case of tinned iron, or tin, as it is commonly called; but this could not be applied on a very large scale, such as for roofing, or for large iron structures, such as have of late been extensively erected for various purposes.

It is not known exactly when zinc coating was first used in France, where it was invented; but the first English patent was taken out in 1837 by Mr H. W. Crawfurd, who applied it chiefly to sheets of corrugated iron, or sheet-iron, bent by a peculiar process into alternate semicircular elevations and depressions; and this soon became extensively employed for roofing purposes, especially for railway sheds, which were then beginning to be in great request.

The process employed by Mr Crawfurd was first to remove the rust and scale from the iron, by immersing it in dilute sulphuric acid, either hot or cold; but the former state was preferred; and for this purpose the acid was kept warm in a large leaden bath, sunk in the ground for easier access. After the sheets or other articles of iron have been acted upon by the acid for a few minutes more or less, according to their requirements, they are plunged into cold water, to remove the acid, and afterwards scoured with sand, and again washed clean with water. The iron being now ready to receive its coating of zinc, it is plunged into a bath of that metal, which, previous to its being melted, is coated with a thick layer of dry sal-ammoniac (hydrochlorate of ammonia); this melts also, and forms a viscid coating over the metal, which prevents that rapid oxidation to which the molten metal is otherwise liable. The bath itself is constructed of fire-clay, and, in some of the large works visited by the writer, contains, when fully charged, from a ton and a half to two tons of molten zinc. The iron is simply dipped into the zinc bath, or made to pass through, and when pulled out is effectually coated.

The enormous demand which has arisen for galvanised iron, especially in the form of sheets, telegraph wire, and bolts for ships, has led to improvements in its preparation; these have been chiefly, however, in the application of machinery to aid the workmen.

Muriatic acid, as well as sulphuric acid, is extensively used in the *pickling* or first process, and for the coarser materials the scouring with sand is usually dispensed with. The sheets are made to pass between two iron rollers in the zinc bath, and are thus more easily drawn through and kept perfectly smooth. Ships' bolts, nails, screws, chains, &c., are dipped in, in bundles, or in the case of nails, &c., in iron strainers; when removed, the zinc makes them adhere together; and to effect their separation, they have to be placed in a crucible with powdered charcoal, in which they are heated to redness, and repeatedly shaken as they cool; by this means, they are easily separated.

The important article of telegraph wire, of which the single firm of Messrs Johnstone & Co., Manchester, annually turns out some thousands of miles, is managed entirely by machinery. The iron wire

is brought from the drawing-mill, and after pickling in dilute muriatic acid, is passed through a pipe kept at white heat by passing through a furnace; this furnace having a row of such pipes set like the tubes of a boiler, but all at the same level, and open at each end, so that the wire has a clear passage through. The machinery being started, the wire is slowly drawn through, and becoming red hot in the pipes, is immediately deflected downwards into the zinc bath between grooved rollers, whence it rises, and is drawn forward; and by the time it is sufficiently cooled, reaches the coiling reels, and is made up into coils ready for use.

There is a variety of galvanised iron called *galvanised tinned iron*. This was introduced by Messrs Morewood and Rogers, who combined several patents to complete their process, which is as follows: A large wooden bath, sufficiently large to hold the largest sheets of iron, is prepared, and the sheets or other articles, after being pickled, and scoured, and washed, as in the usual process, are transferred to it. On the bottom of the bath is first placed a layer of finely granulated zinc, then a sheet of the iron, then another layer of granulated zinc, and so on as far as convenient; and the bath is filled up with a diluted solution of muriate of tin, of the strength of two quarts of the muriate to three hundred gallons of water. The alternate arrangement of zinc and iron constitutes a sort of galvanic battery, which is called into activity by the liquid, and a thin deposit of tin takes place all over the iron, which process is usually completed in about two hours. The plates are then removed from the bath, and after being drained for a short time, are taken to the zinc bath prepared exactly as in the ordinary process, where they are dipped or passed through the rollers. By this process, a very even deposit of zinc is produced, which in cooling, crystallises all over the surface very beautifully; but it is too expensive for the ordinary purposes to which galvanised iron is applied.

Experience has shewn that this material cannot always be used economically; the action of steam upon it produces very rapid decomposition; therefore it is particularly unsuitable for railway stations or sheds under which the locomotives stand and discharge their steam. It was extensively employed for public urinals in Liverpool, and so rapid was their decay, that at the end of three months hardly one was left standing. But if not exposed to a certain class of deleterious chemical influences, it is by far the most economical means of employing iron for covering buildings, as it requires no paint, and withstands the action of the atmosphere for a very considerable length of time.

GALVANISM is that branch of the science of electricity which treats of the electric currents arising from chemical action, more particularly from that attending the dissolution of metals. It is sometimes called *Dynamical Electricity*, because it deals with current electricity, or electricity in motion, and is thus distinguished from *Frictional Electricity* (q. v.), which is called *Statical* in consequence of its investigating the electric condition of bodies in which electricity remains insulated or stationary. These terms, although in the main thus properly applied, are in all strictness applicable to both sciences. Frictional electricity, though small in quantity, can pass in a sensible current, and galvanic electricity, though small in tension, can be made to manifest the attractions and repulsions of stationary electricity. Thus the series of discharges which are transmitted in a wire connecting the prime conductor of a machine in action with the ground, possesses, though feebly, the characteristics of a galvanic current; and the insulated poles of a

many-celled galvanic battery, manifest before the current begins the electric tension of the friction machine. The other branches of current electricity will be found under INDUCTION OF ELECTRIC CURRENTS, MAGNETO-ELECTRICITY, and THERMO-ELECTRICITY.

Historical Sketch.—The science of galvanism dates from the close of the 18th century. In the year 1780, Galvani, in making investigations on the nervous irritability of cold-blooded animals, discovered by accident that the limbs of a recently killed frog, when hung by the crural nerve on a metal support near an electric machine, contracted convulsively at the recurrence of each spark. This he properly accounted for by the back-stroke. See ELECTRICITY. Six years afterwards (1786), in experimenting on atmospheric electricity with frog limbs as delicate electrosopes, he obtained, also accidentally, the same convulsions by bringing the copper hook on which the nerve hung, and the limb itself, simultaneously in contact with an iron railing. The similarity of the result led him to attribute it to the same cause—viz., electricity either existing in the limb itself or produced in the conducting arc of metal. On consideration, he adopted the former hypothesis, and looked upon the limb as a self-charging Leyden jar, with the nerve as the brass knob and wire; the interior of the muscle as the inner coating, its exterior the outer coating, and the metal arc as the discharging tongue. See ELECTRICITY, ANIMAL. He first published his researches in 1791. Volta, 1792, discarded the account given by Galvani of his experiment; and from the fact that the convulsions in question took place with more energy when there were two metals in the conducting arc instead of one, attributed the source of electricity to the heterogeneity of the metals employed. He maintained that at the surface of contact of two different metals an electric force arising from their heterogeneity is generated, which throws them into different tensions. This doctrine forms the fundamental principle of the *contact theory* of galvanism. In reply to Volta, Galvani proved incontestably that the contraction in the limbs of the frog took place when only one metal was employed, and even when the conductor was not of metal at all. Subsequent discovery has proved Galvani to be partly right in attributing the cause of these convulsions to animal electricity, and Volta also to be partly right in attributing them to electricity generated in the metal arc, for both causes may be at work in producing the result. Volta's theory of contact is now, however, generally considered erroneous, and a *chemical theory* better attested by experiment has been originated, which attributes the source of galvanic electricity to the chemical action of a liquid on a metal coupled with another metal less easily acted on than itself. Fabroni, a professor at Florence, was the first (1792) to suggest chemical action as one of the causes at work in Galvani's experiment. Volta did not accept of Galvani's vindication, but supported his theory by several apparently conclusive experiments. In 1799, he constructed, as the crowning evidence of the truth of his reasoning, his pile, and with it properly begins the history of galvanism. To Galvani is thus due the merit of discovering a new manifestation of electricity; to Volta is due the merit of displaying in it a source of power of incalculable importance, and which, but for his genius, might have remained among the barren curiosities of science. Hence it becomes a question of some difficulty to decide to which of the two the science we are discussing owes its origin—whether it is to be called Galvanism or Voltaism. Priority of discovery has led men generally to decide in favour of Galvani, although Volta has

almost equal claim to have his name attached to the science.

The first account of Volta's pile reached England in a letter to Sir Joseph Banks by the inventor (1800). A few weeks afterwards Carlisle and Nicholson decomposed water with it, and afterwards several salts. They were the first to use platinum electrodes. Davy, in the same year, traced the electricity of the pile to chemical action. Wollaston (1801) reiterated the same theory, and went the length of attributing even frictional electricity to chemical action. He proved likewise the identity of the two electricities, and shewed that by diminishing the electrodes to mere points, the electricity of the machine could produce the same chemical effects as that of the pile. In 1802, Cruikshank improved the construction of the pile by disposing the plates horizontally in a trough instead of vertically in column. The main features of electro-chemical decomposition were discussed by Davy in his famous Bakerian lecture of 1806. In 1807, the same philosopher obtained, for the first time by galvanic agency, the metals potassium, sodium, barium, strontium, calcium, and magnesium. Deluc (1809) first made dry piles of gold and silver paper, and these were altered and improved by Zamboni (1812). In 1813, Davy discovered the electric light and voltaic arc (see ELECTRIC LIGHT) by means of the colossal battery then placed at his disposal at the Royal Institution. Ørsted (1820) first observed the action of the current on the magnetic needle; and, a few months afterwards, Ampere discovered the law of this action, and originated an electric theory of magnets which has proved wonderfully fertile in practical results. In the same year Schweigger invented the galvanometer. In 1825, Becquerel, with the aid of his differential galvanometer, investigated the conductivity of metals. Kemp, in 1828, first used amalgamated zinc for the galvanic battery. In 1827, Ohm gave a mathematical theory of the pile, rigidly deduced from Volta's fundamental principle, and in perfect keeping with experiment. Faraday (1831–1832) published his discoveries of the induction of electric currents, and of the evolution of electricity from magnets, which have since enriched the science with the Induction Coil (q. v.) and the Magneto-electric Machine (q. v.). This distinguished electrician discovered (1833–1834) the definite nature of electro-chemical decomposition, and proved that electro-chemical and chemical equivalents were identical. In 1836, Daniell constructed his constant battery. Spenser in England, and Jacobi in Russia, made, simultaneously (1837), the discovery of electro-metallurgy. Grove (1839) constructed his nitric-acid battery. Faraday (1840) proved, apparently beyond dispute, the truth of the chemical theory. Smee's battery dates also from this year. In 1843, Wheatstone, by means of his rheostat and resistance-coils, investigated the resistances offered by various conducting substances to the current. In the same year Bunsen introduced his carbon battery.

The rivalry which has all along existed between the advocates of the chemical and contact theories has been highly conducive to the advancement of the science, each party calling in the aid of invention and discovery to support the truth of their statements. Among the more distinguished contact-theorists may be mentioned Volta, Ritter, Pfaff, Biot, Deluc, Ohm, and Fechner; and among the chemical theorists, Fabroni, Davy, Wollaston, Parrot, De La Rive, and Faraday. Davy latterly maintained a theory of distribution and equilibrium of electricity midway between the two, which numbered among its supporters Jæger, Berzelius, Hermann, and Prechtel.

GALVANIC PAIR.—When two plates of copper and amalgamated zinc (zinc whose surface has been rubbed over with mercury) are placed in a vessel (fig. 1) containing water to which a small quantity of sulphuric acid has been added, so long as

Fig. 1.

they are kept from touching, either within or without the liquid, they remain apparently unaffected. If, however, they be made to touch, bubbles of hydrogen gas are formed in abundance at the copper plate, and their formation continues until the plates are again separated. If the contact be maintained for some time, and the plates and liquid be afterwards examined, it is found that the copper plate weighs exactly the same as before, that the zinc plate has lost in weight, and that the liquid contains the lost zinc in solution in the form of the sulphate of that metal. The contact need not be affected by the plates themselves. If wires of copper, or any other conductor of electricity, be soldered to the plates, or fixed to them by binding screws, and be made to touch, the changes just mentioned take place as if the plates were in contact. When the wires are thus joined, and so to speak, form one connecting wire between the plates, they exhibit very peculiar properties. If a portion of the connecting wire be placed parallel to a magnetic needle, and the needle brought near, its north end no longer points to the north, but to a point either to the east or west of it, and this deviation ceases with the separation of the wires. It is not even necessary that the wires be in contact, for if their ends be put into a vessel containing a conducting liquid, the same changes occur, though to a diminished extent, the contact being completed through the liquid. The ends of the wires, when so immersed, shew strong chemical affinities. If the conducting liquid were a solution of the sulphate of copper, the wire from the zinc becomes coated with the copper of the solution whilst the other attracts its oxygen and sulphuric acid, and wastes away in entering into combination with them. The connecting wires are found, therefore, in actual or virtual combination, to possess very marked magnetic and chemical properties. The arrangement just described constitutes a *galvanic pair*, which may be generally defined to be *two dissimilar conducting plates immersed in a liquid which can act chemically on one of them, and capable of being placed in conducting connection*; and the properties just referred to, form the characteristic powers of galvanic

electricity. These properties arise from the wires in connection being the seat of a constant discharge or flow of electricity, for they are possessed, though to a very feeble extent, by the electricity of the friction electric machine. If the prime conductor of a powerful electric machine (see *ELECTRICITY*) be connected with one of the binding screws of an insulated galvanometer, and a wire connected with the ground be fixed into the other, the plate on being turned causes a current of electricity to pass from the machine to the ground through the coil of the galvanometer, the needle of which will then shew a deviation of one or two degrees. The deviation, so far as direction is concerned, is the same as that which would be produced by placing the wires coming from the copper and zinc respectively in the same binding screws as those connected with the machine and the ground. This would indicate that the copper plate stands electrically in the same relation to the zinc plate as the prime conductor of the machine to the ground. The electricity of the conductor is positive, and that of the ground by induction negative; so that in the galvanic pair the copper plate, by analogy, gives off positive electricity, and the zinc plate negative. Again, let the wire from the machine end in an insulated vessel containing a solution of the sulphate of copper, and let the end of a fine platinum wire connected with the ground be made to dip below the surface of the solution, and let the machine be kept in action so as to send a current of electricity through the wires and liquid, at the end of some minutes the point of the platinum wire will be covered with a minute quantity of copper. The wire connected with the zinc in the galvanic pair and that connected with the ground, are thus shewn to display the same chemical power; and this, again, shews us that the zinc plate, like the ground in the above experiment, is the seat of negative electricity. The electric condition of the plates before contact reveals, with the aid of the condenser, the presence of positive electricity in the copper plate and negative in the zinc plate. If the wire joined to the zinc plate, or as we may write it shortly, zinc wire (not, however, necessarily a zinc wire), be connected with the ground, and the insulated copper wire be made to touch the lower plate of a condenser whilst the finger touches the upper, on both being withdrawn, the leaves of the electroscope diverge with the positive electricity sent to it from the copper plate. It can be shewn, moreover, that the current is not confined to the connecting wire, for if a magnetic needle be suspended between the plates when they lie north and south, slightly above the surface of the liquid, it will deviate from its usual position when the wires are joined, and in the opposite way to that which it shews when held above the wire placed in the same direction. The current thus passes within the liquid from the zinc to the copper the opposite way to that in which it runs in the connecting wires, so that it makes a complete circuit. Hence we may conclude, generally, that in the *galvanic pair* a current of electricity runs within the liquid from the chemically active to the chemically passive plate, and without the liquid, from the chemically passive to the chemically active plate, making a complete circuit; and that if the connection be interrupted the pair shews electric polarity, the *chemically passive plate* being the positive pole, and the *chemically active plate* the negative pole.

The theory of the action of the galvanic pair may be thus given. When the two plates are put into the water and sulphuric acid, they assume opposite electric states. There is developed at the surface of the zinc an electric force arising from its affinity for the oxygen of the water, which throws

the whole arrangement into a state of polarity. This is roughly shewn in fig. 2. The zinc plate with its wire becomes polarised, shewing negative electricity at the extremity furthest from the

Fig. 2.

liquid, and positive electricity at the extremity next the liquid. The copper plate with its wire is polarised in the opposite way, being positive at its outer end, and negative at its end next the liquid. The compound molecules of water (HO), consisting of oxygen (O) and hydrogen (H), are likewise polarised, but the polarisation takes place in the individual molecules. It appears, moreover, to have reference to their compound nature, and we may imagine them placed in series such as the one in the figure, with their oxygen or negative pole toward the zinc, and their hydrogen or positive pole toward the copper. The positive parts are distinguished from the negative parts in the figure by being shaded. When the ends of the wires are brought near each other, we might anticipate in these circumstances that a spark discharge, as with frictional electricity, would restore quiescence. This, however, is not the case, for the electric tension is so low that nothing short of contact can effect a discharge. When the discharge thus takes place, the polarity of the circuit for the instant ceases; the tendency to union of the zinc with the atom of oxygen next it is completed by the formation of the oxide of zinc. But in order to accomplish this, the hydrogen of the molecule of water next the zinc thus set free unites with the oxygen of the neighbouring molecule to re-form water, and the same transference and union is continued along the whole series until the hydrogen of the molecule next the copper is thrown on the copper, where, being unable to unite chemically with it, it assumes its natural gaseous state. In this way the chemical action, although only manifested at the plates, is not confined to them, but takes place throughout the liquid between all the contiguous molecules giving passage to the current. The oxide of zinc formed on the zinc plate is instantly dissolved by the sulphuric acid present in the water, leaving the plate as clean as before. After the first discharge, therefore, the whole arrangement resumes its first condition, so that a second polarisation and discharge instantly follows, which is succeeded by a third, and so on. An uninterrupted series of discharges is thus transmitted along the completed circuit, constituting what is termed a current of electricity.

Nature of the Galvanic Circuit.—In a wire where a current of galvanic or frictional electricity is passing, there is no point which forms the seat of positive or negative electricity, but it appears electrically homogeneous throughout. It exerts no

statical inductive action on surrounding objects neither attracting nor repelling them, for the electric action being more easily propagated along the wire than in any other direction, takes place only in it. The laws of induction and distribution applicable to frictional statical electricity hold true in current electricity only at the section of the wire or conductor along which the action is transmitted. As tested by the magnetic needle there is no part of the circuit which possesses more power than another. This homogeneity gives rise to the hypothesis, that every molecule of the circuit, whether solid or liquid, acts in the transmission of the electric force, and is similarly affected in its passage. In this way the plates and connecting wires shew the same molecular polarity as the liquid, only the discharge does not effect an interchange among the molecules, but leaves them in the same condition as before. Each molecule of the connecting wire may be viewed, as in fig. 3, to be the seat of electric polarity and discharge

Fig. 3.

faces turned towards the copper, and its positive towards the zinc; whenever, therefore, we go with the current, we meet each molecule on its negative side, and whenever we go contrary to the current, we meet each molecule on its positive side. Any portion of the circuit such as that represented in the figure, shews its negative face to the approaching current, and its positive face at the other extremity. A break in the connecting wire thus separates two contiguous molecules; that ending the copper wire shews itself positive, and that ending the zinc wire negative. This is in perfect keeping with experiment, for wherever a break or change of medium is made in the circuit without stopping the current—as in the electric light, chemical decompositions, the visible passage of electricity in vacuous tubes, and the like—the ends or poles exhibit opposite powers, from the pole meeting the current discharging negative, and the other positive electricity. The polarity displayed at such interruptions, or visible passages of the current, is necessarily different from the polarity of frictional electricity, for the dynamical manifestation of electric force cannot be the same as the statical; in the same way that motion, for instance, the dynamical manifestation of the force of gravity is essentially different from weight, its statical manifestation. Within the galvanic pair itself the same polarity is shewn; the zinc plate, without the liquid or the wire connected with it, is found to act as a negative pole, and the similar copper plate and wire as a positive pole; but within the liquid of the cell, the zinc plate shews the same chemical affinities as the exterior positive pole, and the similar copper plate acts as the exterior negative pole. The terms positive and negative poles are merely relative, for every molecule or series of molecules would thus appear to have its opposite poles. They serve, however, conveniently to express the relations of two consecutive parts of the circuit. Considerable confusion sometimes arises from speaking of the zinc plate as at once the positive element and negative pole, and the copper the negative element and positive pole of the galvanic pair, and such expressions seem even inconsistent. The truth is, that the zinc and copper plates must have each both poles from the very nature of the circuit; but as the outer poles only of these plates are of

practical importance, these are considered to be the poles.

According to the one-fluid theory of electricity, a force is developed at the seat of the action, which has the power of liberating the electric fluid, and of maintaining it in motion throughout the circuit, constituting a current in the true sense of the term. According to the two-fluid theory, two such currents, one of the positive the other of the negative fluid, are made to move in opposite directions throughout the circuit. The propelling force is consequently termed *electro-motive*, and the galvanic pair is called the *electromotor*. The terms current and electro-motive have their origin in the supposed fluidity of electricity, but being quite definite in their application, they may be used without any such admission. A current—or, according to the two-fluid theory, a positive current—may be taken to signify, apart from all supposition, simply the peculiar electric condition of the conductor, which forms the line of discharge between a positive and a negative source of electricity, and electro-motive force may be used simply to denote that which propagates and maintains this discharge. In the same way, when we speak of the direction of the current, we only use a convenient way of shewing at which end the positive and negative electricities arise, the current being always represented as moving from the positive to the negative. The greater the electromotive force is, the more powerfully is the discharge effected, and the more is it able to force its way through imperfect conductors. The measure, therefore, of electro-motive force is the tension of the electricity which it generates.

Origin of Galvanic Electricity.—It is now generally admitted that the source of the electro-motive force in the galvanic pair is the chemical action which takes place at the zinc plate. It must appear, even to the most cursory observer, highly probable that the seat of the most active change going forward in the pair is likewise the origin of the force accompanying it. It is found, moreover, when we tax the galvanic current with electro-chemical work, that the amount of work done by it is exactly proportionate to the quantity of zinc dissolved. These and similar considerations seem to argue strongly that galvanic action has its source in chemical action. Volta, however, and several of the most eminent authorities in the science, maintain that the electro-motive force has its seat at the surface of contact of heterogeneous metals, and that chemical action is not the cause, but the manifestation of it. This view of the origin of galvanic electricity is called the *contact theory*, as distinguished from the *chemical theory*, the one we have hitherto followed. The contact theory supposes that at the surfaces of contact of two heterogeneous substances, an electro-motive force, invariable in direction and amount, is generated and subject to modification only by the resistance offered by the conducting circuit. The galvanic pair (fig. 1) is accounted for by this theory in the following way. Let us suppose, for the sake of explanation, that both zinc and copper plates are connected by copper wires. The seat of electro-motive force is at the junction of the copper wire with the zinc. At this point the two metals assume opposite electricities—the copper the negative, and the zinc the positive; and since a conducting circuit through wires, plates, and liquid is established, these electricities travel in opposite directions, and, meeting, neutralise each other within the liquid, to give place to succeeding similar discharges of electricity. The discharge within the liquid takes place electrolytically. The theory is, in this case, sufficient and consistent, but it must be kept in

mind, that in a circuit so perfectly homogeneous, the source of force may be placed anywhere without altering its conditions. The fundamental evidence of the contact theory consists in an experiment like the following: A piece of zinc is made to touch the lower brass or copper plate of a condenser, while the finger rests on the upper. After the zinc and finger are removed, and the upper plate lifted, the gold leaves diverge with negative electricity. Here the mere contact of metals appears to give rise to electricity. The positive electricity of the zinc goes to the ground, and the negative electricity of the copper is insulated in it—the electro-motive force originating at the surface, where the copper and zinc meet. If this experiment were capable only of this interpretation, it would be decisive of the question at issue. It is found, however, that in order to succeed well with it, the fingers must be moist, and that no electricity can be obtained if it be conducted in a gas where no free oxygen is present—such as nitrogen or carbonic acid. Hence it appears, that even in the testing experiment of the contact theory, where it is supposed that contact alone can give any explanation, chemical action, arising from the sweat of the fingers and oxygen of the air acting on the zinc, is present. Faraday's experimental researches seem to place beyond dispute the truth of the chemical theory. We shall here quote two of his many beautiful experiments illustrative of the subject, which are of themselves quite convincing. Let (fig. 4) A and

Fig. 4.

B be two glass vessels containing sulphuret of potassium. Two platinum plates, P and P', are put into the vessel A, and an iron plate F, with a platinum plate P' in B. To the platinum plate P' a platinum wire p, and to the iron plate F an iron wire f, are attached. From P and P', wires proceed to the galvanometer G. The sulphuret of potassium is, for a liquid, a good conductor of electricity, but is chemically inactive when associated with platinum and iron in a circuit. When the wires p and f are joined, if an electro-motive force were developed at their surface of contact, all the conditions necessary for a circuit being present, a current would be generated, which would deflect the needle of the galvanometer. This last, however, gives not the slightest evidence of a current. If zinc be interposed at the junction of p and f, the galvanometer is equally unaffected; but if a piece of paper moistened with sulphuric acid be placed between the ends of these wires, a decided deflection ensues, and the iron becomes the positive element of a platinum-iron pair. We have thus conclusive evidence, that the simple contact of the iron and the platinum is unattended by electro-motive force, and that this is developed only by the chemical action upon the iron of an interposed liquid. Again, into one of the vessels just referred to, let two plates, one of copper, the other of silver, be placed, and let communication be established between them and the galvanometer. The needle at first deflects briskly in a direction which shews that the copper is the positive element

GALVANISM.

of the pair, it then gradually returns to its first position, and again deflects in the opposite direction; shewing that the silver is now the positive element. After some time it returns, and again deflects in the original direction, and goes on thus changing. If the plates be examined during these changes, it is observed that sulphuret of copper is formed when the copper is positive, and sulphuret of silver when the silver is positive; the alternate action being attributable to the relative condition of the plates when coated with their sulphurets. The electro-motive force of a silver copper pair is thus shewn to be not invariable in direction as the contact theorists maintain; but to change its direction with the seat of chemical action.

Chemical conditions of the Galvanic Pair.—We have hitherto supposed that, in the galvanic pair, the zinc alone had affinity for the oxygen of the water, but chemistry teaches us that copper likewise has the same affinity, though to a less degree. Hence we must conclude that there originates at the copper an electro-motive force acting contrary to that of the zinc; and that the electro-motive force of the pair is the difference of these opposing forces. Were we to take two similar plates of zinc instead of one of zinc, and the other of copper, we should thus have two equal forces tending to propel two equal currents in opposite directions. In this case the two forces would equilibrate each other, and electrical and chemical inaction would be the consequence, a conclusion quite in keeping with experiment. It therefore becomes necessary to couple the zinc with a metal such as copper, less oxidable than itself. In keeping with this theory, it is found that if the zinc be coupled with a metal less oxidable still than copper, the resultant electro-motive force is increased. A pair consisting of zinc and silver gives an electricity of higher tension, and consequently a more powerful current than one of zinc and copper, and one of zinc and platinum a stronger current still; silver being less oxidable than copper, and platinum less than silver. As zinc forms the principal element of expense in maintaining the current, a platinum-zinc pair is more economical than either of the other two just named, because, for the same quantity of zinc dissolved, it gives the best electrical result. The greater, then, the disparity in oxidability, or in liability to be affected by the exciting liquid of the metals of the pair, the greater is its power.

In the galvanic cell we have found that not only the metals, but likewise the elements of the liquid, act as if they assumed opposite electricities. The zinc is positive with reference to the copper, and the hydrogen stands in the same relation to the oxygen. In the 'Electro-chemical order of the Elements' (q. v.), the elements are approximately arranged according to the part they would play if associated in a galvanic pair, beginning with potassium, the most electro-positive,* and ending with oxygen, the most electro-negative; each being positive to the one succeeding, and negative to the one preceding it. Chemically speaking, electro-positive has much the same meaning as oxidable. We may here repeat the more common elements in the same order: Potassium, sodium, magnesium, zinc, iron, lead, copper, silver, platinum, hydrogen, carbon, chlorine, sulphur, oxygen. If it were proposed to ascertain from this list the action of a platinum-iron pair immersed in a solution of hydrochloric acid (HCl), we should proceed to argue thus: Iron, preceding platinum, is positive in relation to it. Chlorine succeeds hydrogen, and is relatively negative.

Chlorine, the negative element of the liquid, would accordingly be discharged at the electro-positive iron, and the proto-chloride of iron (FeCl) would be formed. The electro-positive hydrogen would be disengaged at the electro-negative platinum. The interpolar current, consequently, proceeds from the platinum to the iron. If, however, no chemical affinity existed between iron and chlorine, no electricity would be generated, as chemical is essential to galvanic action. From such a list alone we cannot predict the result of any supposed combination. The metals themselves, as we have already seen, frequently change their relative positions, according to the action of the liquid in which they are put, so that the order given is by no means absolute. The electro-negative plate remains in presence of the electro-positive totally unaffected, and more so than if it were placed by itself in the exciting liquid. Hydrochloric acid, for instance, readily attacks iron; but if a piece of zinc be put into the liquid, and be made to touch it, the iron will remain untouched until the zinc has been first dissolved. Wherever, therefore, iron is exposed to corrosive action, it may be protected from it by coupling it with zinc. This accounts, in some degree, for the durability of iron coated with zinc, or, as it is called, 'Galvanised Iron' (q. v.). In the same way zinc protects copper from corrosive action. On the other hand, zinc corrodes more readily in presence of these metals, and hence the necessity for using zinc nails for zinc roofs instead of iron or copper nails. When pure zinc is put into dilute sulphuric acid, almost no change is visible, whilst ordinary commercial zinc is rapidly dissolved by it. This arises, in all probability, from different portions of the latter standing in different chemical relations, arising from the heterogeneous structure introduced by extraneous substances. Galvanic pairs are thus established within the metal, and the metal dissolves in consequence. In a designed galvanic pair, local circuits would thus be formed at different parts of the zinc plate, which, besides occasioning a useless waste of the metal, would lessen the strength of the main circuit, were it not found that amalgamated zinc possesses the properties of the pure metal.

Quantity and Tension of Electricity.—It is found that the tension of the electricity of a galvanic pair, as tested by the amount of divergence of the gold leaves of a condensing electrometer, is not increased by increasing the size of the plates. For the same pair, therefore, metals and liquid included, the electro-motive force is constant whatever be the active surface. Although the tension is not increased, the quantity of electricity transmitted in the current is increased. If the interpolar communication of the two plates be made by a good conductor, such as a thick copper wire, the power which the current has to deflect the magnetic needle is doubled when we double the surface exposed to the action of the liquid. The thick wire offers no resistance to discharge, and the tension of the electricity given off in the two cases is not put to proof. The quantity of electricity is shewn thus to increase with the surface of the plates. The distinction between electricity of quantity and electricity of tension is well illustrated in comparing the electricity of the galvanic pair with that of the machine. A Winter's electric machine, such as the two-foot plate described in the article ELECTRICITY, gives readily, when in good order, a spark of twelve inches, and causes a visible disturbance of the leaves of an electrometer at a distance of 20 feet from it. If such a machine be made to send a current through a moderately sensible galvanometer in the way described at the beginning of the article, it will make the needle deflect one or two degrees. If a galvanic pair be

* According to Bunsen, the new metal, caesium, is the most electro-positive substance yet known.

practical importance, these are considered to be the poles.

According to the one-fluid theory of electricity, a force is developed at the seat of the action, which has the power of liberating the electric fluid, and of maintaining it in motion throughout the circuit, constituting a current in the true sense of the term. According to the two-fluid theory, two such currents, one of the positive the other of the negative fluid, are made to move in opposite directions throughout the circuit. The propelling force is consequently termed *electro-motive*, and the galvanic pair is called the *electromotor*. The terms current and electro-motive have their origin in the supposed fluidity of electricity, but being quite definite in their application, they may be used without any such admission. A current—or, according to the two-fluid theory, a positive current—may be taken to signify, apart from all supposition, simply the peculiar electric condition of the conductor, which forms the line of discharge between a positive and a negative source of electricity, and electro-motive force may be used simply to denote that which propagates and maintains this discharge. In the same way, when we speak of the direction of the current, we only use a convenient way of shewing at which end the positive and negative electricities arise, the current being always represented as moving from the positive to the negative. The greater the electromotive force is, the more powerfully is the discharge effected, and the more is it able to force its way through imperfect conductors. The measure, therefore, of electro-motive force is the tension of the electricity which it generates.

Origin of Galvanic Electricity.—It is now generally admitted that the source of the electro-motive force in the galvanic pair is the chemical action which takes place at the zinc plate. It must appear, even to the most cursory observer, highly probable that the seat of the most active change going forward in the pair is likewise the origin of the force accompanying it. It is found, moreover, when we tax the galvanic current with electro-chemical work, that the amount of work done by it is exactly proportionate to the quantity of zinc dissolved. These and similar considerations seem to argue strongly that galvanic action has its source in chemical action. Volta, however, and several of the most eminent authorities in the science, maintain that the electro-motive force has its seat at the surface of contact of heterogeneous metals, and that chemical action is not the cause, but the manifestation of it. This view of the origin of galvanic electricity is called the *contact theory*, as distinguished from the *chemical theory*, the one we have hitherto followed. The contact theory supposes that at the surfaces of contact of two heterogeneous substances, an electro-motive force, invariable in direction and amount, is generated and subject to modification only by the resistance offered by the conducting circuit. The galvanic pair (fig. 1) is accounted for by this theory in the following way. Let us suppose, for the sake of explanation, that both zinc and copper plates are connected by copper wires. The seat of electro-motive force is at the junction of the copper wire with the zinc. At this point the two metals assume opposite electricities—the copper the negative, and the zinc the positive; and since a conducting circuit through wires, plates, and liquid is established, these electricities travel in opposite directions, and, meeting, neutralise each other within the liquid, to give place to succeeding similar discharges of electricity. The discharge within the liquid takes place electrolytically. The theory is, in this case, sufficient and consistent, but it must be kept in

In a designed galvanic pair, local circuits would thus be formed at different parts of the zinc plate, which, besides occasioning a useless waste of the metal, would lessen the strength of the main circuit, were it not found that amalgamated zinc possesses the properties of the pure metal.

Quantity and Tension of Electricity.—It is found that the tension of the electricity of a galvanic pair, as tested by the amount of divergence of the gold leaves of a condensing electrometer, is not increased by increasing the size of the plates. For the same pair, therefore, metals and liquid included, the electro-motive force is constant whatever be the active surface. Although the tension is not increased, the quantity of electricity transmitted in the current is increased. If the interpolar communication of the two plates be made by a good conductor, such as a thick copper wire, the power which the current has to deflect the magnetic needle is doubled when we double the surface exposed to the action of the liquid. The thick wire offers no resistance to discharge, and the tension of the electricity given off in the two cases is not put to proof. The quantity of electricity is shewn thus to increase with the surface of the plates. The distinction between electricity of quantity and electricity of tension is well illustrated in comparing the electricity of the galvanic pair with that of the machine. A Winter's electric machine, such as the two-foot plate described in the article ELECTRICITY, gives readily, when in good order, a spark of twelve inches, and causes a visible disturbance of the leaves of an electrometer at a distance of 20 feet from it. If such a machine be made to send a current through a moderately sensible galvanometer in the way described at the beginning of the article, it will make the needle deflect one or two degrees. If a galvanic pair be

* According to Bunsen, the new metal, cesium, is the most electro-positive substance yet known.

connector, with the same galvanometer, consisting of very fine iron and copper wires about an eightieth of an inch in diameter, immersed for about an inch into a few ounces of water containing one drop of sulphuric acid, the needle will deflect three or four times what it did before. The electricity of the current produced in the diminutive pair is greater in quantity than that of the machine, but its tension is immeasurably smaller. Should a break be made in the circuit, the power of the terminal poles to attract or repel is almost infinitesimal, and discharge between them through the air cannot be effected even at a microscopic distance. The electricity given off by the machine is small in quantity, but exalted in tension. Could the electricity of the machine have the quantity of that of the pair, or could the electricity of the pair be endowed with the tension of the machine, a current of tremendous power would be the result. The tension of electricity is generally estimated, previous to discharge, by its power of attraction and repulsion, and the quantity, during discharge, by its chemical and magnetic effects.

GALVANIC BATTERY.—When a number of copper and zinc pairs, similar to the one already referred to, are put together, so that the copper plate of one cell is placed in conducting connection with the zinc plate of the next, in the manner shewn in fig. 5, they constitute a galvanic battery. The term battery is sometimes also applied to a number of cells acting as one combination, in whatever way they may be connected. When the terminal copper and zinc plates (fig. 5) are connected, the current runs from

Fig. 5.

each copper to each zinc plate without the liquids, and from each zinc to each copper plate within the liquids; and when the contact is broken, the zinc pole shews negative, and the copper pole positive, electricity. The galvanic battery acts thus in all respects as a compound galvanic pair. If the polar wires be connected with a tangent galvanometer, the deflection of the needle caused by the battery will be exactly the same as that effected by one of the cells, provided the wire be thick, and a good conductor; but if the zinc end be connected with the ground, and the electric tension of the insulated copper pole be tested by a condenser and torsion balance, its tension is found to be as many times greater than the tension of the same pole of one cell examined in the same way, as there are cells in the combination. Thus, if two cells be taken, the tension is doubled; if three, tripled; and so on. *The electro-motive force of a battery is therefore proportional to the number of cells, supposing, of course, that they are arranged consecutively, as in the figure. Hence the electricity of a battery is better able to force its way through imperfect conductors than that of the simple pair. When the interpolar communication is formed by a thick*

short wire, a single cell produces as powerful an effect on the magnetic needle as a battery; but if it be formed by a bad conductor, such as a long and thin wire, or a liquid, the effect is very different. The current of the pair is then nearly stopped, and its influence on the needle small, while that of the battery continues to flow comparatively unimpeded. In the presence of considerable resistance, the quantity of electricity transmitted, or, as it is termed, the *strength* of the current, depends not only on the size of the plates of each couple, but also on the number of couples. That the electric tension should multiply with the number of cells, may be accounted for by the consideration, that instead of one polarising force, there are several, all acting in the same direction, each one exalting the polarity of the molecules produced by the other.

Different Forms of the Galvanic Battery.—Volta's pile is shewn in fig. 6. It consists of a number of circular plates, each made up of a plate of copper and a plate of zinc soldered together, built up, the copper plates facing one way, and the zinc the other, each compound plate being separated by a circular piece of woollen cloth, moistened with a solution of common salt, or dilute sulphuric acid. In consequence of the great number of pairs, the electric tension of the poles of Volta's pile is considerable. One furnished with from 80 to 100 plates can charge an electroscope without the condensing plates. It is from this battery that the term 'pile' is applied to the galvanic or voltaic battery. Volta used another form of battery, which he called a *crowd of cups*. This consisted of a number of cells like those in fig. 1, arranged in a circle, so that the first and last were contiguous.

Fig. 6.

Zamboni's Dry Pile consists of several hundreds, and sometimes thousands, of discs of paper tinned on one side, and covered with binoxide of manganese on the other, put together consecutively, as in Volta's pile, and placed under pressure in an insulating glass tube closed with brass ends, which serve as the poles. The electric tension of the poles of this arrangement is considerable, but the strength of the current which passes when the poles are joined, is next to nothing. The most important application of the dry pile is in the construction of a very delicate electrometer, which is named after its inventor, *Bohnemberger's electrometer*.

The Galvanic Trough, introduced by Cruikshank,

Fig. 7.

is a trough (fig. 7) into which rectangular plates of copper and zinc, like those of Volta's pile, are fixed,

the cells included between each pair being filled with dilute sulphuric acid. The inner surface of the trough is coated with an insulating substance.

Wollaston's Battery.—Each couple of this battery (fig. 8) is made up of a plate of copper, doubled up so as to include a plate of zinc, from which it is kept apart by strips of wood. Both faces of the zinc are thus equally exposed to chemical and galvanic action, a device by which the quantity of electricity is increased. Fig. 9 shews a battery of five of these. The connecting strips of metal are fixed to a wooden rod, which allows of them being lifted or lowered together. When the battery is put in action, the whole is lowered, and the five couples are immersed in five troughs filled with dilute sulphuric acid (1 of the acid to 12 of water).

When out of action, the whole is lifted and fixed by binding screws to the two supporting pillars. When the number of pairs is small, as in

Fig. 9.

the figure, it is of little consequence whether one large trough or five small ones be used.

Smee's Battery.—In Smee's couple, the position of the plates of Wollaston's couple is reversed. It consists of a silver plate, with a zinc plate on either side, kept separated from it by slips of wood, the two zinc plates being fastened by a coupling. There are thus two positive plates to one negative, instead of two negative to one positive, as in Wollaston's couple, and this is found to increase still more the strength of the current produced. The silver plate is platinised—that is, covered over with finely divided platinum—and this is found to lessen the adhesion of the hydrogen bubbles to the plate, thereby greatly improving the constancy of the action. Smee's battery has the same arrangement as Wollaston's.

Grove's Gas Battery.—This battery is more intended for instruction than use. One of its cells is shewn in fig. 10. Into the two outer necks of a three-necked bottle, two glass tubes are fitted by means of corks through which they pass. Each of these tubes is open below, and a platinum wire enters them hermetically above, to which a long strip of platinum is soldered, extending nearly to the bottom of the tube. Little cups containing mercury stand at the upper ends of these wires. The whole apparatus is filled with slightly acid water, and the poles of a galvanic battery are placed in the little cups. Water is thereby decomposed: oxygen forms in the one tube and hydrogen in the other. When the battery wires

are removed, no change takes place till metallic connection is established between the cups, and the oxygen and hydrogen gradually disappear, attended by an electric current which passes from the oxygen to the hydrogen. When several of these are put together in a battery, the connection being always oxygen to hydrogen, they can decompose water. The most important fact illustrated by Grove's battery is, that the oxygen and hydrogen, liberated by galvanic agency, when left to themselves, produce a current the opposite to that which separated them. When the poles of the decomposing battery were in the mercury cups, hydrogen is given off at the negative, and oxygen at the positive pole; and as opposite electricities attract, it is manifest that the hydrogen in this action is positive, and the oxygen negative. When the two gases form, by means of the platinum plates, a galvanic pair by themselves, the current must proceed, as in all cases, from the positive to the negative within the liquid, and the reverse way between the poles; but this is the opposite of the direction of the original current. It is therefore manifest that where oxygen or hydrogen is set free at any point in a galvanic circuit, they will tend to send a counter-current. This action is called *galvanic polarisation*. This accounts for the sudden falling off in strength in all galvanic couples where hydrogen is set free at the negative plate. The bubbles of the gas adhering to the plate, not only lessen the surface of contact between the plate and the liquid, but exert an electromotive force contrary to that of the pair, and this goes on increasing until the action becomes greatly reduced. In all improved forms of the pair, it therefore becomes necessary to adopt some means for preventing the disengagement of hydrogen at the negative plate, and this is done in all *constant batteries* by employing two fluids instead of one. The best known constant batteries are those of Daniell, Grove, and Bunsen.

Fig. 10.

Fig. 11.

Fig. 12.

Daniell's Battery.—A cell of this battery is shown in fig. 11, and a section of it in fig. 12. The

containing vessel, *c*, is of copper, which serves likewise as the negative element of the pair. Inside of this is another vessel, *d*, of porous unglazed earthenware containing a rod of zinc, *z*. The space between the copper and the porous cell is filled with a solution of the sulphate of copper, which is kept concentrated by crystals of the salt lying on a projecting shelf, *s*, and dilute sulphuric acid is placed with the zinc in the porous cell. When a tangent galvanometer is included in the circuit, the needle keeps steadily at the same point for hours. The rationale of its action is given as follows: the porous cell which keeps the fluids from mingling, does not hinder the passage of the current; when the atoms of hydrogen that would ultimately be freed at the copper reach the porous cell, they displace the copper in the sulphate of copper, and copper instead of hydrogen is thrown on the copper plate. To give a graphic representation of this action, it is necessary to suppose that the sulphate of copper (CuO, SO_4) should be represented not as the union of oxide of copper (CuO) and sulphuric acid (SO_4), but as CuSO_4 , the direct combination of the metal (Cu) with a salt radical (SO_4) called sulphion, and that the dissolution of the zinc does not arise from the decomposition of water, but of the compound of sulphuric acid and water (HO), regarded as the sulphionide of hydrogen (H, SO_4). Taking these letters to represent the molecules, and beginning with the copper (Cu) of the outer vessel, and ending with the zinc (Zn) of the rod, we have the arrangement before discharge, $\text{Cu}, \text{CuSO}_4, \text{CuSO}_4,$

$\text{H}, \text{SO}_4, \text{H}, \text{SO}_4, \text{Zn}$; and after it, $\text{CuCu}, \text{SO}_4, \text{CuSO}_4, \text{H}, \text{SO}_4, \text{H}, \text{SO}_4, \text{Zn}$. The discharge, therefore, effects a deposition of copper at the copper, and the formation of sulphionide of hydrogen at the porous cell, and of sulphionide of zinc at the zinc rod. Instead of hydrogen in its nascent state being deposited at the copper, we have copper in the same condition; but the galvanic polarisation caused by the latter is very much inferior to that resulting from the former, and hence the superior electromotive force of Daniell's cell. The porous cell keeps the sulphate of zinc from reaching the copper, and thus obviates another source of diminished force in the one-fluid battery. The sulphate of zinc once formed, is itself subjected to the decomposing action of the pile, and zinc is deposited on the copper-plate, thus tending to give a zinc-zinc instead of a copper-zinc pair. The constancy of Daniell's battery is not unlimited, for the sulphate of zinc which results from the action, being a bad conductor of electricity, enfeebles the current. From its great specific gravity, however, it falls to the bottom of the cell, and may be removed by a siphon, and replaced by fresh liquid. A battery of Daniell's cells is put up in the usual way.

Grove's Battery consists of platinum-zinc couples. Fig. 13 shows an excellent arrangement of a cell of it. The outer cell of glass, *g*, is filled with dilute sulphuric acid (1 part of acid to 8 of water), in which a cylindrical plate of zinc, *z*, is immersed. Inside the zinc is a porous cell, *d*, containing concentrated nitric acid and the platinum plate, *p*, which is bent into the form of an S (fig. 14), to increase its surface. Grove's couple is very much superior in power to any of the preceding, though it is inferior in constancy to Daniell's. When the poles are joined, sulphate of zinc is formed in the outer cell, and hyponitric acid (NO_2) vapours are given off by the nitric acid. As these vapours are injurious to the health when breathed for any time, the porous cell is closed with a stopper of wood, to prevent or lessen their escape, the connection between the exterior and the platinum plate being made by a strip of metal passing through the wood. The

chemical action of Grove's couple may be shewn in the same way as Daniell's, taking nitric acid (NO_3)

Fig. 13.

Fig. 14.

to be the oxide of hyponitric acid (NO_2). Before discharge, the molecules stand thus, beginning with the platinum: $\text{Pt}, \text{NO}_3, \text{O}, \text{NO}_3, \text{O} | \text{H}, \text{SO}_4, \text{H}, \text{SO}_4, \text{Zn}$; and after it, $\text{Pt}, \text{NO}_2, \text{O}, \text{NO}_2, \text{O} | \text{H}, \text{SO}_4, \text{H}, \text{SO}_4, \text{Zn}$. The hyponitric acid gas (NO_2) discharged at the platinum plate is absorbed by the nitric acid, in which it is soluble, so that the plate is left free. The cells of a Grove's battery are connected with the platinum of the one to the zinc of the other.

Bunsen's Battery.—Bunsen's cell has the same chemical action as Grove's, the platinum being replaced by carbon. There are two forms of the cell—the one invented and employed by Professor Bunsen, and generally adopted in Germany; and the modification introduced by Archemau, generally found in England and France. The Bunsen cell, properly so called, has a carbon cylinder immersed in nitric acid, and the porous cell containing the zinc and sulphuric acid placed within it. Fig. 15

Fig. 15.

represents a battery of four cells, shewing how the different cells are connected: *g* is the containing glass vessel; *c*, the carbon cylinder; *d*, the porous cell; and *z*, the zinc. The other form of the Bunsen cell is shewn in fig. 16. In it the same arrangement is adopted as in Grove's cell. The latter form of the Bunsen cell, in consequence of the preponderance of the positive surface, gives the greater quantity of electricity. For the manufacture of the Bunsen carbons, see CARBON FOR ELECTRIC PURPOSES. Bunsen's battery, in point of cheapness, is preferable to Grove's, where the platinum forms an expensive item, but is inferior to it in point of compactness. In these couples, the platinum and carbon may be

replaced by iron, which is nearly as electro-negative as either in concentrated nitric acid. In Müller's *Physik*, the following numbers are given as the relations of the electromotive forces of the different

Fig. 16.

couples: Bunsen's, 800; Grove's, 780; Daniell's 470; and Wollaston's, 208.

GALVANOMETERS.—The two most reliable evidences of the strength of the galvanic current are, its power to deflect the magnetic needle, and to effect chemical decomposition. To measure one or other of these, is the object of a galvanometer or voltameter. A magnetic galvanometer shews the strength of the current by the amount of the deflection of the needle, and shews its direction by the way in which it deflects. The manner in which a needle should turn when influenced by a current is easily kept in mind by Ampere's rule: *Suppose the diminutive figure of a man to be placed in the circuit, so that the current shall enter by his feet, and leave by his head; when he looks with his face to the needle, its north pole always turns to his left.* The deflecting wire is supposed always to lie in the magnetic meridian. The *Astatic Galvanometer*, or *Galvanometer*, is used either simply as a galvanoscope, to discover the existence of a current, or as a measurer of the strengths of weak currents. When a needle is placed under a straight wire, through which a current passes, it deflects to a certain extent, and when the wire is bent, so as also to pass below the needle, it deflects still more. This is easily understood from the above rule. The supposed figure has to look down to the needle when in the upper wire, and to look up to it in the lower wire, so that his left hand is turned in different ways in the two positions. The current in the upper and the lower wire moves in opposite directions, thus changing in the same way as the figure; and the deflection caused by both wires is in the same direction. By thus doubling the wire, we double the deflecting force. If the wire, instead of making only one such circuit round the needle, were to make two, the force would be again doubled, and if several, the force (leaving out of account the weakening of the current caused by the additional wire) would be increased in proportion. If the circuits of the wire be so multiplied as to form a coil, this force would be enormously increased. Two needles, as nearly the same as possible, placed parallel to each other, with their poles in opposite ways, as shewn in fig. 17, and suspended, so as to move freely, by a thread without twist, have little tendency to place themselves in the magnetic meridian, for the one would move in a contrary direction to the other. If they were exactly of the same power, they would remain indifferently

in any position. They cannot, however, be so accurately paired as this, so that they always take up a fixed position, arising from the one being somewhat stronger than the other.

This position is sometimes in the magnetic meridian, sometimes not, according as the needles are less or more perfectly matched. Such a

Fig. 17.

compound needle is called *astatic*, as it stands apart from the directing magnetic influence of the earth. If an astatic needle be placed in a coil, as in fig. 17, so that the lower needle be within the coil, and the upper one above it, its deflections will be more considerable than a simple needle, for two reasons: in the first place, the power which keeps the needle in its fixed position is small, and the needle is consequently more easily influenced; in the second place, the force of the coil is exerted in the same direction on two needles instead of one, for the upper needle being much nearer the upper part of the coil than the lower, is deflected alone by it, and the deflection is in the same direction as that of the lower needle. An astatic needle so placed in a coil constitutes an astatic galvanometer. One of these instruments is shewn in fig. 18. Round an ivory

Fig. 18.

bobbin, AB, a coil of fine copper wire, carefully insulated with silk, is wound, its ends being connected with the binding screws, a, d'. The astatic needle is placed in the bobbin, which is provided with a vertical slit, to admit the lower needle, and a lateral slit, to allow of its oscillations, and is suspended by a cocoon thread to a hook supported by a brass frame. The upper needle moves on a graduated circle; the compound needle hangs freely, without touching the bobbin. The whole is included in a glass case, and rests on a stand, supported by three levelling screws. When used, the bobbin is turned round by the screw, Q, until the needle stands at the zero point, and the wires through which the current is sent are fixed to the binding screws. The number of degrees that the needle deflects may then be read off. It is manifest that on deflection taking place, the different portions of the coil are differently situated with respect to the

needle, than when it is at zero; the deflecting force of the coil, therefore, differs with the position of the needle, so that the deflections caused by different currents are not in the proportion of the angles of deviation, or their functions; up to from 15° to 20° , it is found for most instruments that the strength of the current is proportional to the angle of deviation; beyond that, the relations of strength indicated by different angles must be ascertained experimentally, which can be done with the aid of a thermo-electric pile.

Tangent Galvanometer.—This instrument is shown in fig. 19. It consists essentially of a thick strip

Fig. 19.

of copper, bent into the form of a circle, from one to two feet in diameter, with a small magnetic needle, moving on a graduated circle, at its centre. When the needle is small compared with the ring, it may be assumed that the needle in any direction it lies holds the same relative position to the disturbing power of the ring. This being the case, it is easy to prove that the strengths of currents circulating in the ring are proportional to the tangents of the angles of deviation of the needle. Thus, if the deflection caused by one galvanic couple was 45° , and of another 60° , the relative strengths of the currents sent by each would be as the tangent of 45° to the tangent of 60° —viz., as 1 to 1.73. The needle can never be deflected 90° , for as the tangent of 90° is infinitely large, the strength of the deviating current must be infinitely great, a strength manifestly unattainable. The tangent galvanometer can consequently be used to measure the strongest currents. One great advantage attending its use, is that the current, in passing through the thick copper wire, experiences almost no resistance, and consequent diminution of strength, so that it can measure a current without affecting it.

Voltmeter.—This was invented by Faraday for testing the strength of a current. Fig. 20 shows how it may be constructed. Two platinum plates, each about half a square inch in size, are placed in a bottle containing water acidulated with sulphuric acid; the plates are soldered to wires which pass

the gas formed within. When the binding screws are connected with the poles of a battery, the water in the bottle begins to be decomposed, and hydrogen and oxygen rise to the surface. If, now, the outer end of the discharging tube be placed in a trough of mercury (mercury does not dissolve the gases), and a graduated tube (fig. 21), likewise filled with mercury, be placed over it, the combined gases rise into the tube, and the quantity of gas given off in a given time measures the strength of the current. The voltmeter chooses as a test the work which the current can actually perform, and establishes a uniform standard of comparison. The indications of the tangent galvanometer are comparable only with its own, but the quantity of gas discharged by the voltmeter, corrected for pressure and temperature, is something quite absolute. However, by comparing the indications of both instruments with each other when placed in the same circuit, an absolute standard may likewise be got for the tangent galvanometer. If, for instance, the current given by a battery should give 2 cubic inches in a minute, as shown by the voltmeter, and produced at the same time a deflection of 45° in the galvanometer, the ratio of 2 to the tangent of 45° —viz., 2 to 1 = 2, is constant, for correct measurements of the strength of currents, however taken, must bear to each other a constant ratio. If the angle of deviation for another current was 30° , we have therefore only to multiply 2 by the tangent of 30° , to ascertain the amount of gas that would be liberated by a current of that strength in a minute. This found, we know the meaning of a deflection of 30° of the galvanometer in question in a perfectly comparable standard. The plates of the voltmeter must be small, for when they are large, a small quantity of electricity is found to pass without decomposing the water. It is found also that a minute quantity of the oxygen forms binoxide of hydrogen with the water, and remains in solution, so that when very great accuracy is required, the hydrogen alone ought to be measured.

RESISTANCES TO THE CURRENT.—It is found that the dimensions and material of substances included in the circuit exercise an important influence on the strength of the current. It is of the greatest importance to ascertain the relative amount of the resistance offered by conductors of various forms and materials. The rheostat, invented by Wheatstone, is generally employed for this purpose, and for this object is constructed so as to introduce or withdraw a considerable amount of highly resisting wire from the circuit without stopping the current. It is shown in fig. 22. Two cylinders, C, C, about 6 inches in length, and $1\frac{1}{4}$ inch in diameter, are placed parallel to each other, both being movable round their axis. One of them, C, is of brass, the other, C, is of well-dried wood. The wooden cylinder has a spiral groove cut into it, making forty turns to the inch, in which is placed a fine metallic wire. One end of the wire is fixed to a brass ring, which is seen in the figure at the farther end of the wooden cylinder; and its other end is attached to the nearer end (not seen in the figure) of the brass cylinder, C. The brass ring just mentioned is connected with the binding screw, S, by a strong metal spring. The further end of the cylinder C, has a similar

Fig. 21.

Fig. 20.

up through the cork of the bottle; binding screws are attached to the upper ends of these wires; a glass tube fixed into the cork serves to discharge

the gas formed within. When the binding screws are connected with the poles of a battery, the water in the bottle begins to be decomposed, and hydrogen and oxygen rise to the surface. If, now, the outer end of the discharging tube be placed in a trough of mercury (mercury does not dissolve the gases), and a graduated tube (fig. 21), likewise filled with mercury, be placed over it, the combined gases rise into the tube, and the quantity of gas given off in a given time measures the strength of the current. The voltmeter chooses as a test the work which the current can actually perform, and establishes a uniform standard of comparison. The indications of the tangent galvanometer are comparable only with its own, but the quantity of gas discharged by the voltmeter, corrected for pressure and temperature, is something quite absolute. However, by comparing the indications of both instruments with each other when placed in the same circuit, an absolute standard may likewise be got for the tangent galvanometer. If, for instance, the current given by a battery should give 2 cubic inches in a minute, as shown by the voltmeter, and produced at the same time a deflection of 45° in the galvanometer, the ratio of 2 to the tangent of 45° —viz., 2 to 1 = 2, is constant, for correct measurements of the strength of currents, however taken, must bear to each other a constant ratio. If the angle of deviation for another current was 30° , we have therefore only to multiply 2 by the tangent of 30° , to ascertain the amount of gas that would be liberated by a current of that strength in a minute. This found, we know the meaning of a deflection of 30° of the galvanometer in question in a perfectly comparable standard. The plates of the voltmeter must be small, for when they are large, a small quantity of electricity is found to pass without decomposing the water. It is found also that a minute quantity of the oxygen forms binoxide of hydrogen with the water, and remains in solution, so that when very great accuracy is required, the hydrogen alone ought to be measured.

Fig. 22.

connection with the binding screw, S'. The key, H, fits the projecting staple of either cylinder, and can consequently turn both. As the brass cylinder, C', is turned in the same direction as the hands of a watch, it uncoils the wire from the wooden cylinder, C, making it thereby revolve in the same way. When the wooden cylinder is turned contrary to the hands of a watch, the reverse takes place. The number of revolutions is shewn by a scale placed between the two, and the fraction of a revolution is shewn by a pointer moving on the graduated circle, P. When the binding screws, S and S', are included within a circuit, say S with the positive, and S' with the negative pole, the current passes along the wire, on the wooden cylinder, C, till it comes to the point where the wire crosses to the brass cylinder, C'; it then passes up the cylinder, C', to the spring and binding screw, S'. The resistance it encounters within the rheostat is met only in wire, for as soon as it reaches the large cylinder, C', the resistance it encounters up to S' may be considered as nothing. When the rheostat is to be used, the whole of the wire is wound on the wooden cylinder, C, the binding screws are put into the circuit of a constant cell or battery along with a galvanometer, astatic or tangent. If, now, the resistances of two wires are to be tested, the galvanometer is read before the first is put in the circuit. After it is introduced, in consequence of the increased resistance offered by it, the needle falls back, and then as much of the rheostat wire is unwound as will bring the needle back to its former place. The quantity of wire thus uncoiled in the rheostat is shewn by the scales, and is manifestly equal in resisting power to the introduced wire. The first is then removed, the rheostat readjusted, and the second wire included, and the same unwinding goes on as before. To fix our ideas, let the quantity of wire unwound in the first case be 40 inches, and in the second case 60 inches; 40 inches of the rheostat wire offer as much resistance to the current as the first wire, and 60 inches of it as much as the second. We have thus 40 to 60 as the ratio of the resistances of the two wires. The wire of the rheostat, from its limited length, can only be comparable with small resistances; and where great resistances are to be measured, supplementary resistance coils of wires, whose resistances have been ascertained, are introduced into the circuit, or removed from it, as occasion requires, leaving to the rheostat to give, as it were, only the fractional readings. This being premised, it will be easily understood how the following results have been ascertained. It is proved, for instance, that the resistances of wires of the same material, and of uniform thickness, are in the direct ratio of their lengths, and in the inverse ratio of the squares of their diameters. Thus a wire of a certain length offers twice the resistance of its half, thrice of its third, and so forth. Again, wires of the same metal, whose diameters stand in the ratio of 1, 2, 3, &c., offer resistances which stand to each other as 1, $\frac{1}{4}$, $\frac{1}{9}$, &c.; therefore, the longer the wire the greater the resistance; the thicker the wire the less the resistance. The same holds true of liquids, but not with the same exactness. For this reason, the larger the plates of a galvanic pair, and the nearer they are placed to each other, the less will be the resistance offered to the current by the intervening liquid. The following table, constructed by Ed. Becquerel, gives the specific resistances of some of the more common substances, or the resistance which a wire of them, so to speak, of the same dimensions, offers at the temperature 54° F.: Copper, 1; silver, .9; gold, 1.4; zinc, 3.7; tin, 6.6; iron, 7.5; lead, 11; platinum, 11.3; mercury (at 57°), 50.7. For liquids,

the resistances are enormous as compared with the metals. With copper at 32° F. as 1, the following liquids stand thus: Saturated solution of the sulphate of copper, at 48° F., 16,885,520; ditto of chloride of sodium at 56° F., 2,903,538; sulphate of zinc, 15,861,267; sulphuric acid, diluted to $\frac{1}{4}$, at 68° F., 1,032,020; nitric acid, at 55° F., 976,000; distilled water, at 59° F., 6,754,208,000. The slightest admixture of a foreign metal alters the resistance very decidedly: $\frac{1}{4}$ per cent of iron in copper wire increases the resistance more than 25 per cent. It has been found also that the resistance offered by a wire increases as its temperature rises. It is almost needless to add, that the conducting powers of metals are inversely as their specific resistances, the least resisting being the best conducting.

Ohm's Law.—This law is singularly in accordance with experimental results. It assumes that the electro-motive force for a particular galvanic pair is constant, and that the strength of the current it produces is the quotient which results from dividing it by the resistance of the circuit. This resistance arises from two sources, the first being the resistance within the cell offered by the exciting liquid, and the second the interpolar resistance. If e represent the electromotive force; l , the resistance within the cell; w , the interpolar resistance; and S , the strength of the current, or the quantity of electricity actually transmitted, the statement of the law for one couple stands thus: $S = \frac{e}{l + w}$. The applica-

tion of the law in a few particular cases will best illustrate its meaning. If we increase the number of cells to n , we increase the electromotive force n times, and at the same time we increase the liquid resistance n times, for the current has n times as much of it to travel, then $S = \frac{ne}{nl + w}$. If w be small compared with nl —that is, if the external connection be made by a short thick wire—it may be neglected, and so $S = \frac{ne}{nl} = \frac{e}{l}$. This shews that one

cell gives in these circumstances as powerful a current as a large battery. But if nl be small with respect to w —as in the interpolar circuit of an electric telegraph battery— nl may be neglected, and $S = \frac{ne}{w}$. Here we learn that the energy of the

current increases directly as the number of cells. We may learn from the same that the introduction of the coil of long thin wire of a galvanometer into such a circuit, introducing but a comparatively small increase of resistance, causes a very slight diminution of the current strength. If, again, we increase the size of the plates of a galvanic pair n times, the section of the liquid is proportionately increased, so that whilst the electro-motive force remains the same, the cell resistance diminishes n times; therefore $S = \frac{e}{l + \frac{w}{n}}$, or

$S = \frac{ne}{l + nw}$. If the exterior resistance is small, nl may be neglected, and $S = \frac{ne}{l}$, and the strength

is thus shewn to increase n times. These are only a very few of the conclusions arrived at by this law. With the aid of a tangent galvanometer, which gives the value of S expressed in cubic inches of voltameter gas, we can easily ascertain the value of e and l for any pair. By making two observations with two wires of known resistance separately included in the circuit, we have two simple

GALVANISM.

equations with two unknown quantities, from which r and l can be easily found. In doing so, we must adopt a *unit of resistance*, such as that proposed by Jacobi—viz., that offered by a copper wire 1 metre (39·3 inches) long, and 1 millimetre (0·0393 inch) in diameter. The resistance of the liquid of the pair would be expressed in units of this, and the electromotive force in cubic inches of explosive gas with a circuit offering a unit of resistance.

THE EFFECTS OF THE GALVANIC CURRENT may be classified under physiological, mechanical, magnetic, heating, luminous, and chemical. The mechanical effects relate to the mutual attraction or repulsion of one current to another, or to a part of itself. These, along with the magnetic effects, will be found treated of under MAGNETO ELECTRICITY. The heating and luminous effects have been partly discussed under ELECTRIC LIGHT. We shall here only further refer to the heating of wires, and to the galvanic spark. The luminous effects of galvanic electricity of very high tension will be given under INDUCTION COIL. The chemical effects have been already referred to, but a fuller consideration of these will now be given under the head *Electrolysis* in this article.

The *physiological effects*, as shown by the convulsions of Galvani's frog preparation, were the first observed manifestation of the current. Frog-limbs, as prepared by Galvani, when included in a circuit, form a galvanoscope of excessive sensibility, which rivals the finest galvanometer in delicacy of indication. There is one peculiarity in their action which deserves to be noted. The limbs contract only when the circuit is completed and broken, and remain undisturbed so long as the current passes steadily through them. The more frequently, therefore, the current is stopped and renewed, the greater is the physiological effect. The same is experienced when a current is passed through the human body. When the terminal wires of a battery are lifted one by each hand, except it consist of a very large number of cells, almost the only sensation felt is a slight shock on completing and breaking the circuit. Du Bois Reymond, the great authority on animal electricity, states that the nerves of motion are affected only by changes in the electric tension of the current, whereas the nerves of sensation are affected not only by these, but also by the steady continuance of the current, and that the excitation of the nerves dependent on the changes of tension increases with their frequency and suddenness. Frictional electricity in this way owes its superior physiological power to the instantaneous nature of its discharge. It is only currents of great tension which affect the ordinary human nerves. The poles of a battery of 50 Bunsen cells, capable of giving a brilliant electric light, for instance, may be handled without much inconvenience. This may be attributed partly to the non-conducting nature of the skin. If the current enter the body by a cut or wound, the sensation is affected even when the current is weak. The physiological effect is also much heightened by moistening the hands with salt and water, or by holding metal handles instead of wires, so as to improve the conducting connection. Another cause of this insensibility may be attributed to the fact that the current is not restricted, as it is in part of the frog preparation, to the nerve, but passes through all the conductors of the system. The nerves of the palate can be affected by a very feeble current; that of sight by one proceeding from a battery of one or two cells, and that of hearing by a battery of some 30 cells. See ELECTRICITY, MEDICAL.

Heating Effects.—When a strong current passes through thin wires, an intense heat is produced,

sufficient to bring them to a white heat, and to fuse them. This is turned to practical use in exploding gunpowder, in engineering and mining operations. Two wires of a battery placed at a safe distance are insulated from each other, and their ends, which are connected by a fine iron wire, are sealed up in a tin cartridge filled with gunpowder, and laid in the exploding charge. When all is adjusted, the battery connection is completed, and the current making the iron wire red hot, ignites the gunpowder in the cartridge, and that again the charge. In this way, all danger is avoided. Experiments on the heating effects of the current through wires have proved that *the heat developed is proportional to the resistance of the wires, and to the squares of the strength of the currents; and that the strength of the current being the same, any length of wire may be heated to the same redness.*

Galvanic Spark.—When the wires connected with a powerful galvanic battery are brought together, no current passes except they are made to touch, or nearly so; and if then separated, the current continues with the evolution of sparks, though removed for some distance. Jacobi found that the poles of a battery of twelve Grove's cells could be brought as near as 0·0005 of an inch without a spark passing. In Gassiot's water battery of 3520 well-insulated cells, however, a spark passed when the poles were brought to 0·2 of an inch, and continued to do so uninterruptedly for weeks and months together. When the galvanic spark is examined with a microscope, it is found that the light only appears at the negative pole.

Electrolysis is that branch of the science of galvanism which treats of the laws and conditions of electro-chemical decomposition. As this decomposition is generally attended by electro-chemical combination, it is sometimes difficult to distinguish electrolysis from the more general subject of *Electro-chemistry*, which embraces all chemical changes resulting in or from the galvanic current. In one case, however, the application of the term is strictly correct—viz., where decompositions are effected by electrodes (poles, see ANODE), which are not attacked by the elements of the electrolyte (the substance decomposed) discharged at them. Throughout the article, there have been frequent allusions to electro-chemical changes, but here we shall discuss more particularly the laws of electro-chemical decomposition. No substance is decomposed by the current so long as it is in a solid or gaseous state, and it must first be brought to a liquid state, either by solution or fusion, before the current acts on it. The decomposition of water by platinum plates is always taken as the type of electrolytic action. Fig. 23 represents a very convenient apparatus for the purpose. A glass basin is made so as to admit a cork below, through which two wires pass having slips of platinum plate soldered to them above. Two glass tubes, open below, are hung over the plates, to hooks projecting from an upright support. The bowl is

Fig. 23.

Two glass tubes, open below, are hung over the plates, to hooks projecting from an upright support. The bowl is

filled with acidulated water; and the tubes, after being filled with the same, are inverted, and hung with their lower ends enclosing the plates. When the wires projecting downwards from the cork are connected with the poles of the battery, hydrogen rises from the negative, and oxygen from the positive electrode, to fill each its separate tube. As the decomposition proceeds, twice as much hydrogen is liberated as oxygen. When the tubes are filled, they may be removed and examined. The oxygen thus obtained smells strongly of ozone. Hydrogen is here the type of the metals or other electro-positive substances (cations), which, during electrolysis, are always disengaged at the negative electrode; and oxygen of the salt radicals, chlorine, iodine, sulphur, &c., which, being electro-negative (anions), always appear at the positive pole. Moreover, the proportions of the volumes of the two gases being that of their chemical combining volumes, reminds us that, when a body is decomposed, its components are always separated in the proportions in which they were united, viz., those of their chemical equivalents. If the tubes of this apparatus were graduated, it would serve for a voltameter. If, instead of one such voltameter included in the circuit, we had several, we should find that, whatever amount of gas was liberated in one of these, the same amount would be liberated in all, and that independent of the size of the plates, and amount of acid in each. We learn, therefore, that the chemical power of the current is the same at every point of the circuit where it is manifested. If, instead of two or three voltameters in the circuit, we had one and two decomposing cells of the following description. A test tube, having a platinum wire, on which the glass has been fused, passing through the bottom, is partially filled with protochloride of tin, which is kept fused by the heat of a spirit-lamp. The platinum wire at the bottom of the tube forms one electrode, and one descending from the top forms the other, dipping below the fused chloride. If, then, this cell be included in the circuit along with the voltameter, and a similar cell containing fused chloride of lead, so that the current enters the tubes by the upper electrodes, and leaves by the lower, the water, protochloride of tin, and chloride of lead, are decomposed simultaneously by the current passing through each. In the voltameter, hydrogen and oxygen are disengaged; in the tubes, metallic tin is deposited at the lower electrode of the one, and lead at the other; whilst chlorine is liberated at the upper electrodes of both. If, now, the quantity of hydrogen, tin, and lead thus set free be weighed, it will be found that their weights are in the proportion of their chemical equivalents. From such experiments as these, Faraday made the first grand electrolytic generalization to the following effect: *When the current passes through a series of binary electrolytes, consisting of an equivalent of each of the elementary bodies, the quantities of the separated elements of the electrolytes are in the same proportion as their chemical equivalents.* It is not only in cells exterior to the battery that this law holds, but in the cells of the battery itself. If the battery which effected the above decomposition consisted of six cells, for each equivalent of hydrogen, tin, and lead separated without the battery, one equivalent of zinc in each cell would have been dissolved, and an equivalent of hydrogen disengaged at each of the copper plates, if the cells were one-fluid. The above law holds also for binary compounds, whose elements do not stand in the relation of an equivalent of the one to an equivalent of the other, but with this modification, that the weights of the electro-negative elements alone, separated in the action, are in the ratio

of their equivalents. Thus, if the same current pass through two decomposing cells, one containing a solution of the subchloride of copper (Cu_2Cl), and the other of the chloride of copper (CuCl), the same quantity of chlorine will be disengaged in both, but twice as much copper is deposited in the first as in the second. Had there been a sesquichloride of copper (Cu_3Cl_2) in the same way for one equivalent of chlorine disengaged, there would be $\frac{2}{3}$ of an equivalent of copper. Daniell proved, in extension of Faraday's law, that the binary constituents of the oxisalts followed the same law as binary elementary compounds; he shewed that, if a voltameter, and a vessel divided into two compartments by a porous diaphragm, both containing sulphate of soda (NaO, SO_3), be included in the same circuit, after some time, the compartment into which the positive pole dips contains free sulphuric acid (SO_3), and that the other compartment contains free soda (NaO); and the hydrogen and oxygen of the voltameter, and the soda and sulphuric acid of the sulphate of soda, when weighed, stand in the ratio of their chemical equivalents. The decomposition here taking place was found to be the same in all similar salts. One effect of the decomposition in the above instance, however, seemed singular—nearly as much oxygen and hydrogen was decomposed at the electrodes as in the voltameter, so that the current appeared to do double work within the cell. To account for this anomaly, Daniell suggested a new theory of oxisalts, to which we have already referred in passing. According to it, sulphate of soda (NaO, SO_3) should not be looked upon as such, but as sulphionide of sodium (NaSO_3), a binary salt similar to the chloride of sodium (NaCl); with this difference, that, in the former case, the salt radical sulphion (SO_3) was compound, and in the latter it was simple (Cl). This being the case, the primary stage of decomposition will be, the metal sodium (Na) set free at the negative, and the sulphion (SO_3) at the positive electrode; but sodium being highly oxidable, cannot preserve its metallic condition in the presence of water; it therefore decomposes the water, taking its oxygen, and setting free its hydrogen, so that the hydrogen does not come directly from electrolytic action, but from a purely chemical *secondary action*—viz., that of sodium on water. The sulphion (SO_3) breaks up into sulphuric acid (SO_3), which remains in solution, and oxygen (O), which escapes. This view of the matter appeared to him to be borne out by the fact that, when a similar salt of a less oxidable metal, the sulphate of copper, for instance, is exposed to the same action, the copper retains its metallic condition, and no hydrogen escapes at the negative electrode; sulphate of copper (CuO, SO_3) is in this way more properly sulphionide of copper (CuSO_3). Similarly, nitrate of soda (NaO, NO_3) is NaNO_3 , nitronide of copper, and the like composition is given to all oxisalts. This view of the composition of salts reduces all electrolytes to the same general formulae, such as MR , M_2R_2 , &c.; M being a metal, or electro-positive constituent, and R a salt radical, or electro-negative; and the electrolytic law might be given thus: *When the same current passes through a series of electrolytes, the weights of the separated electro-negative constituents are to each other as their chemical equivalents.* The accuracy of the electrolytic law is somewhat compromised by the fact that liquids possess, to a certain extent, the power of conducting, physically, electricity without electrolytic action, so that all that passes in this way is chemically lost. Fortunately, the error thus introduced is very small, and can be therefore practically disregarded.

ELECTRO-METALLURGY is the art of depositing, electro-chemically, a coating of metal on a surface

prepared to receive it. It may be divided into two great divisions—electrotype and electro-plating, gilding, &c., the former including all cases where the coating of metal has to be removed from the surface on which it is deposited, and the latter all cases where the coating remains permanently fixed. Gold, platinum, silver, copper, zinc, tin, lead, cobalt, nickel, can be deposited electrolytically.

Electrotype—the art of copying seals, medals, engraved plates, ornaments, &c., by means of the galvanic current in metal, more especially copper. The manner in which this is done will be best understood by taking a particular instance. Suppose we wish to copy a seal in copper: an impression of it is first taken in gutta percha, sealing-wax, fusible metal, or other substance which takes, when heated, a sharp impression. While the impression—say, in gutta percha—is still soft, we insert a wire into the side of it. As gutta percha is not a conductor of electricity, it is necessary to make the side on which the impression is taken conducting; this is done by brushing it over with plumbago by a camel-hair brush. The wire is next attached to the zinc pole of a weakly charged Daniell's cell, and a copper plate is attached by a wire to the copper pole of the cell. When the impression and the copper plate are dipped into a strong solution of the sulphate of copper, they act as the negative and positive electrodes. The copper of the solution begins to deposit itself on the impression, first at the black-leaded surface in the vicinity of the connecting wire, then it gradually creeps over the whole conducting surface. After a day or two, the impression is taken out; and the copper deposited on it, which has now formed a tolerably strong plate, can be easily removed by inserting the point of a knife between the impression and the edge of the plate. On the side of this plate, next the copper, we have a perfect copy of the original seal. If a medal or coin is to be taken, we may proceed in the same way, or we may take the medal itself, and lay the copper on it. In the latter case, the first cast, so to speak, that we take of each face is negative, showing depressions where the medal shows relief; but this is taken as the matrix for a second copy, which exactly resembles the original. The adhesion between the two is slight, and they can be easily separated. The cell of a battery is not needed to excite the current. A galvanic pair can be made out of the object to be coated and a piece of zinc. Fig. 24 shows how this may be done. B is a glass vessel, containing sulphate of copper; A is another, supported on B by a wire-frame, and containing a weak solution of sulphuric acid. The glass vessel, A, is with-

Fig. 24.

out a bottom, but is closed below by a bladder. A piece of zinc, Z, is put in the sulphuric acid, and a wire, D, coated with insulating varnish, establishes a connection between it and the impression, C, which is laid below the bladder. Electrotype is of the greatest importance in the arts; by means of it, engraved copper plates may be multiplied indefinitely, so that proof-impressions need be no rarity; wood-cuts can be converted into copper; bronzes can be copied; and several like applications are made of it too numerous to mention. By connecting a copper plate ready for corrosion with the positive pole, and making it a positive

electrode, it can be etched with more certainty than with the simple acid, and without the acid fumes.

Electro-plating.—This is the art of coating the baser metals with silver by the galvanic current. It is one theoretically of great simplicity, but requires in the successful application of it very considerable experience and skill. Articles that are electro-plated are generally made of brass, bronze, copper, or nickel silver. The best electro-plated goods are of nickel silver. When Britannia metal, iron, zinc, or lead are electro-plated, they must be first electro-coppered, as silver does not adhere to the bare surfaces of these metals. Great care is taken in cleaning the articles previous to electro-plating, for any surface impurity would spoil the success of the operation. They are first boiled in caustic potash, to remove any adhering grease; they are then immersed in dilute nitric acid, to dissolve any rust or oxide that may be formed on the surface; and they are lastly scoured with fine sand. Before being put into the silvering bath, they are washed with nitrate of mercury, which leaves a thin film of mercury on them, which acts as a cement between the article and the silver. The bath where the electro-plating takes place is a large trough of earthenware or other non-conducting substance. It contains a weak solution of cyanide of silver in cyanide of potassium. A plate of silver forms the positive electrode; and the articles to be plated, hung by pieces of wire to a metal rod lying across the trough, constitute the negative electrode. When the plate is connected with the copper or positive pole of a one or more celled galvanic battery, according to the strength required, and the rod is joined with the zinc or negative pole, chemical decomposition immediately ensues in the bath, the silver of the cyanide begins to deposit itself on the suspended objects, and the cyanogen, liberated at the plate, dissolves it, re-forming the cyanide of silver. According, then, as the solution is weakened by the loss of the metal going to form the electro-coating, it is strengthened by the cyanide of silver formed at the plate. The thickness of the plate depends on the time of its immersion. The electric current thus acts as the carrier of the metal of the plate to the objects immersed. In this way, silver becomes perfectly plastic in our hands. We can by this means, without mechanical exertion or the craft of the workman, convert a piece of silver of any shape, however irregular, into a uniform plate, which covers, but in no way defaces, objects of the most complicated and delicate form. When the plated objects are taken from the bath, they appear dull and white; the dullness is first removed by a small circular brush of brass wire driven by a lathe, and the final polish is given by burnishing. The process of electro-gilding is almost identical with that of electro-plating. Success in either is attained by proper attention to the strength of the battery, the strength of the solution, the temperature, and the size of the positive electrode.

GALVESTON, a city and seaport of the state of Texas, North America, is situated on the north-east extremity of Galveston Island, at the opening of the bay of the same name into the Gulf of Mexico; lat. 29° 18' N., long. 94° 50' W. It is the largest and most commercial city of Texas. Its harbour, the best in the state, has 12 feet of water over the bar at low tide. Its streets are straight, spacious, and elegant; and its principal buildings—the Roman Catholic University of St Mary's, the Roman Catholic Cathedral, and the Episcopal Church—are large, imposing edifices of brick in the Gothic style. G. has also numerous churches, a convent of Ursuline nuns, and a number of

GALWAY.

schools of various kinds. Here nearly all the foreign trade of the state is transacted. In 1858, 61 foreign vessels, of 26,373 tons, entered and cleared the port; but the greater proportion of the trade is along the coast. In 1856, the number of entrances of coasting-vessels was 3594, 1065 being steamers, regular lines of which ply from this town to New York and New Orleans, as well as to the south-west towns of Texas. The principal trade is in shipping cotton, of which from 300,000 to 400,000 bales were exported in 1859. The town has good wharfs, several ship-building yards, foundries, machine-shops, cotton-presses, &c. Population estimated in 1850 at 4177; in 1859, at 10,000. The Bay of Galveston extends northward from the city to the mouth of Trinity River, a distance of about 35 miles, and is from 12 to 18 miles broad. The island of Galveston is a long strip of low-lying ground with a mean elevation of from 3 to 4 feet above sea-level, and is about 28 miles long, and from $1\frac{1}{4}$ to $3\frac{1}{4}$ miles broad. It was, from 1817 to 1821, the haunt of the notorious pirate Lafitte, who was dislodged in the latter year, and his settlement broken up.

GALWAY, a municipal and parliamentary borough of Ireland, a seaport, and county of itself, stands at the mouth of the river Corrib, on the north shore of Galway Bay, 50 miles north-north-west from Limerick, and 130 miles west-south-west from Dublin. It is built on both sides of the river, and on two islands in its channel, its parts being united by two bridges. It is connected with Lough Corrib by a canal, and forms the terminus of the Midland Great Western Railway. A line of steamers has, with a few interruptions, run for the last four years between G. and the North American colonies, seven days being considered the usual time for a fair passage. The old town of G. is poorly built and irregular, and some of its older houses have a somewhat Spanish appearance, which is accounted for by the commercial intercourse which at one time subsisted between G. and Spain. To one of these houses, which is marked with a skull and cross-bones, a very remarkable story is attached, of a mayor of G., James Lynch Fitzstephen, who, in 1493, like Brutus of old, condemned his own son to death for murder, and in order to prevent his being rescued, actually caused him to be hanged from his own window. The new town consists of well-planned and spacious streets, and is built on a rising-ground, which slopes gradually toward the sea and the river. The suburbs are mainly collections of wretched cabins, inhabited by a miserably poor class of people. One of these suburbs, called Claddagh, is inhabited by fishermen, who exclude all strangers from their society, and marry within their own circle. These fishermen still speak the Irish language, and the Irish costume is still worn by the women. They annually elect a 'mayor,' whose function it is to administer the laws of their fishery, and to superintend all internal regulations. One of the principal buildings of G. is the parish church of St Nicholas, founded in 1320, in connection with which is an ecclesiastical body called the Royal College of Galway, consisting of a warden and eight vicars choral, who are elected by the Protestant members of the corporation. In the Roman Catholic Church a similar ecclesiastical arrangement formerly existed. The see of Enachdune, of which G. formed a part, was united to that of Tuam in 1324; but in 1484, G. was constituted a wardenship, with a distinct jurisdiction, similar to that of an episcopal see. The wardenship, in later times, was held by one of the bishops of the neighbouring sees. The right of electing the warden, however, was vested in certain

Catholic clans or families of the town—Blakes, Bodkins, Lynches, Frenches, &c.—who, by a curious local custom were distributed into 13 tribes. This singular system, almost without example in the Catholic Church, continued in use until about 30 years ago; when, in 1831, the wardenship of G. was erected into an episcopal see, the bishop of which is appointed by the same rules which regulate other Episcopal appointments in Ireland. Among the other edifices are three monasteries and five nunneries; the Queen's College, opened in 1849; Erasmus Smith's College, with an endowed income of £126 a year; the county court-house; barracks, &c. G. has numerous flour and other mills, also breweries, distilleries, foundries, &c., extensive salmon and sea fishing, a good harbour, with docks that admit vessels of 600 tons, and a light-house. The exports consist mainly of corn, flour, bacon, fish, kelp, and marble. In 1861, 369 vessels, of 98,255 tons, entered and cleared the port. G. returns two members to parliament. Pop. (1861) of town, 16,786; of parliamentary borough, 24,990; which shews a decrease, since 1851, of 7001 in the former, and of 9156 in the latter.

G. was taken by Richard de Burgo in 1232, and the ancestors of many of the leading families now resident in this quarter settled here about that time. From the 13th till the middle of the 17th c., G. continued to rise in commercial importance. During the latter part of the 17th c., it suffered considerably for its adherence to the royalist cause. In 1652, it was taken by Sir Charles Coote after a blockade of several months; and in July 1691, it was compelled to surrender to General Ginkel.

GALWAY, a maritime county of Ireland, forms the southern portion of the province of Connaught, and is second in size of all the Irish counties, Cork being the largest. It is bounded on the E. by two navigable rivers, the Shannon, and its affluent the Suck; and on the W. by the Atlantic Ocean. It has an area of 1,566,354 acres, of which the one half is arable, and almost the whole of the remainder uncultivated. Pop. (1851) 297,897, (1861) 254,256. The county of G. is watered in the east by the Shannon, the Suck, and their feeders; and in the west by Loughs Mask and Corrib, and by the streams—none of them of any great importance—which fall into the loughs and into Galway Bay. In the most southern portion of the county are the Slieve-Baughta Mountains; and in the west are the well-known Twelve Pins, a striking mountain group, with a general height of about 2000 feet; and the Maam-Turk mountains, of about an equal height. This western portion of the county is exceedingly wild and romantic; the hills are separated by picturesque glens, and by secluded and beautiful loughs. South-west from Lough Corrib to the sea is the district called Connemara, which contains vast bogs, moors, lakes, and morasses, and presents a peculiarly bleak and dreary aspect. North-east of Connemara is Joyce's Country, and south-east of it is Iar-Connaught, or Western Connaught. The coast-line is stated to be about 400 miles in length, and the shore is much broken, and is fringed with numerous islands. On the coasts of Connemara (*Cun-na-mar*, 'bays of the sea') and Iar-Connaught, there are more harbours for vessels of large size than on any equal extent of coast perhaps in Europe. The climate is mild and humid, and in low-lying localities, is sometimes unhealthy. The richest soil occurs in the district between the head of Galway Bay and the Shannon. Agriculture and fishing are the most general pursuits; kelp is largely manufactured; also woollens, linens, friezes, felt hats, are manufactured. The lakes and loughs, as well as the coasts of G., are well stocked with fish. The

county of G. abounds in ancient remains of the Celtic as well as of the English period. *Raths* and *cromlechs* are numerous; monastic ruins are found in all parts of the county; a very fine specimen of this class is that of Knockmoy, near Tuam; and there are no fewer than seven round towers in the county. G. county sends two members to parliament.

GALWAY BAY, an inlet of the Atlantic Ocean, on the west coast of Ireland, between the counties of Galway and Clare. It is a noble sheet of water, and offers great facilities for an extended commerce. Great efforts have been made to obtain a public grant for the construction of a harbour of refuge; and a company was formed in 1858 for the establishment of the Transatlantic packet-service alluded to in the article GALWAY. A series of misadventures, however, has hitherto attended its efforts; but it is hoped that its operations will be resumed with greater vigour in the present year (1862). G. B. is 30 miles in length from west to east, and has an average breadth of about 10 miles. At its entrance, and between the North and South Sounds, are the islands of Arran.

GALYZIN, or **GOLYZIN**, also frequently **GALIZIN**, **GALITZIN**, or **GALLITZIN**, one of the most numerous, powerful, and distinguished Russian families. It derives its origin from the Lithuanian prince Gedimin, the founder of the Jagellonian dynasty of rulers in Poland, Hungary, and Bohemia. Among the leading members of the family may be mentioned—1. The princes **MICHAEL** and **DIMITRI G.**, Russian commanders under Wassili IV., grand-duke of Warsaw, who were taken prisoners by the Poles at the battle of Orscha in 1514. Dimitri died in captivity, and Michael was only released after a confinement of 38 years.—2. **WASSILI G.**, surnamed the Great, born in 1633, was the councillor and favourite of Sophia, the sister of Peter the Great, and regent during his minority. Wassili was a man of liberal culture and civilised tastes. His great aim was to bring Russia into contact with the west of Europe, and to encourage the arts and sciences in the native gymnasia, and at the court itself. His design to marry Sophia, and plant himself on the Russian throne, however, miscarried. Sophia was placed by her brother in a convent, and Wassili was banished to a spot on the Frozen Ocean, where he died of poison.—3. **BORIS G.**, cousin of the previous, was Peter the Great's tutor, and one of the administrators of the kingdom during the czar's first journey abroad.—4. **DIMITRI G.**, also a cousin of Wassili's, was a distinguished Russian statesman; ambassador at the Turkish court; afterwards director of the imperial finances; and finally head of the reform party of Galyzin and Dolgoruki, which wished to limit the absolute authority of the czar. Dimitri's plan failed; the two families were banished, and Dimitri himself ended his days in the dungeons of Schlüsselburg.—5. **MICHAEL G.**, born about 1675, was brother of Dimitri, and one of the most distinguished Russian generals. He was the inseparable companion of Peter the Great in all his campaigns. His most famous achievement was the conquest of Finland. He died at Moscow, 1730.—6. **DIMITRI G.**, born 1738, went as Russian ambassador to France in 1763, and to Holland in 1773. He died in 1803. He wrote one or two books, but he owes the preservation of his name mainly to his wife, the celebrated **AMALIE**, PRINCESS G., daughter of the Prussian general, Count von Schmetsau. This lady (born at Berlin, August 28, 1748) was remarkable for her literary culture, her grace and amiability of disposition, her sympathetic relations with scholars and poets, but, above all, by her ardent pietism,

which found its most congenial sphere in the mystic and venerable sanctities of Roman Catholicism. Having separated from her husband, she took up her residence in Münster, where she gathered round her a circle of learned companions. Here resided for a longer or shorter time Von Fürstenberg, Goethe, Jacobi, and others, but her most attached friends were Hemsterhuis and Hamann. She is the *Diótima* to whom the former of these, under the name of Dioklas, addressed his *Lettre sur l'Éthisme* (1785). She largely contributed to the conversion of Count Stolberg and his family to Roman Catholicism, and called forth that excess of religious feeling which for a considerable period characterised many circles of German society, and which Voss so sharply reproved in his *Wie ward Fritz Stolberg ein Unfreier* (How Fritz Stolberg became a Slave). The Princess Amalie died August 24, 1806.—Compare *Denkwürdigkeiten aus dem Leben der Fürstin Amalie von G. (Münster, 1828)*.—7. **DIMITRI AUGUSTINE G.**, son of the foregoing, was born at the Hague, December 22, 1770. He became a Roman Catholic in his 17th year, shortly after his mother; and through the influence exercised over him by a clerical tutor during a voyage to America, he resolved to devote himself to the priesthood. In 1795, Dimitri Augustine was ordained a priest in the United States by Bishop Carroll of Baltimore, and betook himself to a bleak region among the Alleghany Mountains, in Pennsylvania, where he was known as 'Father Smith.' Here he laid the foundation of a town, called Loretto, which has now a population of 6000. He was austere as regards his personal mode of life, but liberal in the highest degree to others, and an affectionate and indefatigable pastor. He wrote various controversial works, some of which are still largely read in the United States. We may mention his *Defence of Catholic Principles, Letter to a Protestant Friend, and Appeal to the Protestant Public*. He died at Loretto, May 6, 1840.—8. **PRINCE EMANUEL G.**, born in Paris, 1804, studied in that city, and afterwards entered the Russian army. He translated into French Wrangel's book on Northern Siberia, and wrote an interesting work, entitled *La Finlande. Notes recueillies en 1848* (2 vols., Paris, 1852). He died at Paris, February 1853.

GAMA, **DOM VASCO DA**, the discoverer of the maritime route to India, was born, it is not precisely known when, at Sines, a small seaport of Portugal. He was descended of an ancient family, which was even supposed to have royal blood in its veins, though not legitimately. At an early period, he distinguished himself as an intrepid mariner; and after the return of Bartolommeo Diaz, in 1487, from doubling the Cape of Good Hope, King João, in casting about for a proper man to undertake the discovery of a southern passage to India, fixed on G., so great was the confidence which his abilities inspired. The intentions of João were frustrated by death; but his successor, Manoel the Fortunate, fitted out four vessels, manned altogether with 160 men, and intrusted them to the command of G., presenting him at the same time with letters to all the potentates whom it was thought likely he might require to visit; among others, one to the mythical 'Prester John,' then supposed to be reigning in splendour somewhere in the east of Africa. The little fleet left Lisbon 8th July 1497, but having been tormented by tempestuous winds almost the whole way, only arrived at the haven now known as Table Bay on the 16th of November, where they cast anchor for a few days. On the 19th November, G., after encountering a series of frightful storms, and being obliged to sternly suppress a mutiny among his terrified crew, who wanted him to return

to Portugal, sailed round the southern extremity of Africa, and touched at various places on the hitherto unknown eastern coast of Africa. At Melinda, where he found the people far more civilised than he expected, he obtained the services of a well-educated pilot, a native of Guzerat, in India, who seemed familiar with the astrolabe, the compass, and quadrant. Under his guidance, G. struck out to sea, crossed the Indian Ocean, and arrived at Calicut, in India, on the 20th of May 1498. His reception by the ruler of Calicut (the 'Samudri-Rajah,' or Prince of the Coast, shortened into Zamorin) was not very favourable, nor did G.'s intercourse with him subsequently improve. The Arab merchants residing there were jealous of the new-comers, who might interfere with their monopoly of traffic, and incited the Hindus against them. Other complications also arose, and the result was that, on his departure, G. had to fight his way out of the harbour. Satisfied with the discoveries he had made, the Portuguese commander now turned his course homeward, touched at several of the places he had previously visited, and in September 1499, cast anchor at Lisbon, where he was received with great distinction. High-sounding titles were conferred on him. He was allowed the rare privilege of prefixing *Dom* to his name, and obtained a large indemnity for his trouble, besides certain monopolies in the commerce about to be opened with India. King Manoel immediately despatched a squadron of 13 ships, under Pedro Alvarez Cabral, to India, for the purpose of establishing Portuguese settlements in that country. In this they were successful only in a few places. At Calicut, forty Portuguese, who had been left behind, were murdered by the natives. To avenge this injury, and, more particularly, to secure the Indian Ocean commerce, the king fitted out a new squadron of 20 ships, which set sail under G.'s command in 1502. This fleet reached in safety the east coast of Africa, founded the Portuguese colonies of Mozambique and Sofala, which still exist, and sailed to Travancore. On his way, G. captured a richly laden vessel filled with Mussulmans from all parts of Asia, on their way to Mecca. He barbarously set it on fire; and the whole crew, amounting to about 300, were burned or slain, with the exception of some 20 women and children. What adds to the tragic character of this fearful incident is, that it occurred through a mistake. G. confounded these Asiatic followers of the Prophet with the Moors of Africa, the hereditary enemies of his nation, and proceeded to extremities on that assumption. On reaching Calicut, G., after a delay of a few days, bombarded the place, destroyed a fleet of 29 ships, and compelled the rajah to conclude a peace with suitable indemnification. If this act of vengeance or of punishment, executed as it was with prudence and determination, inspired the natives with fear of the power of the Portuguese, it contributed to confirm the alliances made with several of the native princes. So rapid had been G.'s proceedings, that before the close of December 1503, he was back in Portugal with 13 richly laden vessels. He was not, however, again employed for a period of 20 years; and it would appear that Manoel, for some reason or other, failed properly to appreciate his great services. Meanwhile, the Portuguese conquests in India increased, and were presided over by five successive viceroys, while G. was lying inactive at home. The fifth of these viceroys, however, was so unfortunate, that King João III., the successor of Manoel, was compelled to have recourse to the old hero; and in 1524, bearing the title of viceroy, G. set sail once more for the scene of his former triumphs with a fleet of

13 or 14 vessels. As he approached the coast of India, an unaccountable agitation of the water was observed by all. There was no wind to cause it, and the superstitious sailors were greatly alarmed. 'Why fear?' said G.: 'the sea trembles before its conquerors.' His firmness and courage succeeded in making Portugal once more respected in India; but while engaged in his successful schemes, he was surprised by death at Cochin, December 1525. His body was conveyed to Portugal, and buried with great pomp. In the character of G., resolution was found combined with prudence and great presence of mind. His justice, loyalty, honour, and religious fervour distinguished him above most of the great navigators and conquerors of his time. His discovery of a passage to India almost vies in importance with the discovery of America by Columbus, which took place only a few years before. Consult Barros, *Decades*; Castanpeda and Lafitau, *Hist. Conqu. Portug.*; and Cooley, *Hist. Mar. Discov.* His achievements are also celebrated by Camoens in the *Lusiad*.

GAMA GRASS (*Tripsacum*), a genus of Grasses, distinguished by unisexual flowers placed in spikes, which are fertile at the base, and barren towards the extremity, the spikelets having two glumes and about two florets, the female florets immersed in the thick and sinuous joints of the rachis, so that the spike, when the seed is ripened, presents the appearance of a cylindrical bone. Only two species are known, of which *T. dactyloides*, the Gama Grass of Mexico, distinguished by having spikes usually three together, has a high reputation as a fodder-grass, and is cultivated not only in Mexico, but in the United States of America, and now also to some extent in Europe. In favourable circumstances, it yields a very abundant crop, and attains a height of nine or ten feet, its root-leaves measuring six feet in length. It possesses what for some climates is an almost invaluable property of bearing excessive drought without injury. It suffers, however, from frost. It seems eminently adapted to the climate of the Australian colonies.—The other species, the Gama Grass of Carolina (*T. monostachyon*), distinguished by solitary spikes, is not so much esteemed.—Gama Grass is said to derive its name from a Spanish gentleman who first attempted its cultivation in Mexico.

GAMA'LIEL, the Greek form of the Hebrew name *Gaml'el* (*My rewarder is God*; or, *Mine also is God*), the most celebrated bearer of which is Gamaliel I., or the Elder (*hasaken*), probably the one mentioned in the New Testament (Acts, v. 34, and xxii. 3). Both here and in the Talmudical writings, he appears only in his capacity of a teacher of the law, and a prominent Pharisaic member of the Sanhedrim (q. v.); but of the circumstances of his life, or the date of his birth and death, we learn nothing from these, the only sources. He was the son of Simeon, the same, it may be assumed, who was first honoured by the title of Raban (our master)—a mark of distinction afterwards bestowed on Gamaliel himself—and thus the grandson of the celebrated Hillel. Whether (as would follow from Pesachim, 88 b.) he actually presided over the Sanhedrim (in the reigns of Tiberius, Caligula, and Claudius) or not, certain it is that the laws and ordinances which were issued by that body during his life bore the stamp of the all-embracing humanity and enlightened liberality which from the 'regal' House of Hillel was transferred to the School of Hillel—principally as opposed to the particularising and austere school of Shamai. To the refinement and erudition hereditary in his family—to which, alone, on account of its exalted

position, even in the otherwise strictly forbidden study of Greek science and philosophy had been allowed (cf. Derech Eretz, iv.).—G. appears to have added a rare degree of discretion, and of that practical wisdom which betimes revokes or adapts social laws, according to the wants of the commonwealth. For the benefit of sufferers of all kinds, that most stringent law of the limited Sabbath-day's journey was relaxed; the licence hitherto allowed to the absent husband, of annulling his letter of divorce (if he regretted his rashness), even after its delivery, before any court of two or of three men, was abolished (Gittin, 32); while, on the other hand, to prevent confusion, preense or involuntary, the strictest accuracy with respect to the names of the husband, wife, and witnesses contained in these documents was most rigorously enforced. Again, the widow was to receive her marriage-portion (Ketuba) from the recalcitrant heirs, simply on her asseveration that she had not received it during her husband's lifetime: while formerly she had not been permitted to make oath even in the matter (Gittin, 34). But no less important, and testifying, at the same time, to a spirit free from prejudice, are the other laws respecting the treatment of the Gentiles, which may properly be ascribed to G.'s influence, if indeed they were not inaugurated by himself. Gentile and Jew, it was enacted, should henceforth, without distinction, be allowed the gleanings of the harvest-field; even on the day specially set aside to his idol-worship, the former should be greeted with the salutation of peace. Of his poor, the same care was to be taken; his sick were to be tended, his dead to be buried, his mourners to be comforted, exactly as if they belonged to the Jewish community (Gittin, 59 b., 61 ff.; Jer. Gitt. c. 5)—certainly no mean tribute to the principle of the equality of the human race, and a practical carrying out of Hillel's motto, the words of the Scripture (Lev. xix. 18), 'And thou shalt love thy neighbour as thyself' (cf. Sabbath, 30 b. ff.). The consideration of these and other legislative acts, all tending towards that social improvement and consolidation (*Tikkun Haolam*) which was G.'s avowed and acknowledged aim, seems also to set at rest that old and barren dispute, whether G., when he interposed on behalf of the apostles, and referred their matter to God himself, was secretly a Christian, or whether he was 'a cowardly tyrant, who even sought to withhold from them the privilege of martyrdom.' Tolerant, peaceful, as free from fanaticism on the one hand, as on the other from partiality for the new sect, which he seems to have placed simply on a par with the many other sects that sprang up in those days, and disappeared as quickly: he exhorts to long-suffering and good-will on all sides. Of his relation to St Paul, of the 'Law' he taught him (Acts, xxii. 3), as well as of the influence which his mind might have exercised over that of the 'apostle of the Gentiles,' we shall treat under the name of this latter.

When G. died (about seventeen years before the destruction of the Temple), 'the glory of the law' was said to have departed, and with him 'died the reverence before the law and the purity of the abstinences' (Pharisaism), (Sota, 49). His memory has always been held in the highest honour. The story of his conversion to Christianity, we need scarcely add, is as devoid of any historical foundation as that of the transmission of his bones to Pisa. In conclusion, it may be mentioned, that G. has been placed on the list of Christian Saints, and that his day is celebrated on the 3d of August.

GAMB, an heraldic corruption of the French word *jambe*, the leg. See JAMBE.

GAMBA. See VIOL DI GAMBA.

GA'MBESON, or WAMBEYS, a word of doubtful origin, implying a covering for the body, was the name of a thickly quilted tunic stuffed with wool, and worn by knights under the hauberk, as a padding for the armour. As it was sufficiently strong to resist ordinary cuts, it was sometimes worn without other armour. The surcoat was also quilted or *gamboused* with cotton wool, as in that of the Black Prince, still hanging above his tomb in Canterbury cathedral.

GA'MBIA, a river of Western Africa, whose basin, and that of the Senegal, constitute the region known as Senegambia, enters the Atlantic in lat. 13° 30' N., and long. 16° 34' W., after an estimated course of fully 1000 miles. It is four miles broad at its mouth, having a reach of double the width immediately inside. It is navigable for vessels of 150 tons up to Barraconda, a town on its right bank, about 200 miles from the sea.

GAMBIA, a British settlement occupying the banks of the river of the same name, as far up as Barraconda, though not continuously. The principal station, Bathurst, is situated on the island of St Mary, at the mouth of the Gambia. Other posts are Fort James and Fort George, the former also situated on St Mary's, and the latter on MacCarthy's Island, 180 miles from the sea. Pop. of settlement in 1861, 5693, of whom 191 were whites. The climate is comparatively unhealthy. The export trade, already considerable, is steadily increasing, comprising chiefly wax, hides, ivory, gold dust, rice, palm-oil, horns, timber, and ground-nuts. The last-named article alone had augmented from 10,868 tons, value £130,496, in 1856, to 15,705 tons, value £188,464, in 1858. The foreign commerce with France, Great Britain, and the United States, respectively employs 12,500, 5500, and 3800 tons. In 1855 there were in this settlement seven schools, attended by 1349 pupils.

GA'MBIER ISLANDS, a Polynesian group, under a French protectorate, in lat. 23° 8' S., and long. 134° 55' W. They number five larger, and several smaller islands, all of coral formation. With the exception of Pitcairn's Island, they alone, on the route between Chili and Tahiti, yield good water in sufficient abundance for the supply of shipping.

GA'MBIR, or GAMBEER, an astringent substance resembling CATECHU (q. v.), and used for the same purposes. It is one of the most powerful of pure astringents. It is prepared from the leaves of the G. shrub, *Uncaria Gambir*, a native of the East Indies and Malay Archipelago. The genus *Uncaria* belongs to the natural order *Cinchonaceæ*. The G. shrub is very extensively cultivated in the Eastern Archipelago, great quantities of G. being used by the Malays for chewing with betel. G. is obtained by boiling or infusing the leaves in water, and evaporating either by the heat of a fire or of the sun. It is used in Europe both in medicine, and extensively in tanning. It is often called *Terra Japonica* in commerce. When examined by the microscope, it is found to consist in great part of a multitude of small crystals of *catechine*.

GAMBLING, or GAMING, the art or practice of playing a game of hazard, or one depending partly on skill and partly on hazard, with a view, more or less exclusive, to a pecuniary gain. Games of this nature were forbidden by the Romans both under the Republic and the Empire (Cic. *Philipp.* ii. 23; *De leg.* ix. tit. 5; *Cod.* iii. tit. 43). The ground

on which this was done was the tendency of such practices, not to demoralise the populace, but to render them effeminate and unmanly. Horace (*Carm.* iii. 24) complains that youths of condition, instead of riding and hunting, had betaken themselves to illegal games of chance. It belonged to the sediles to attend to the public interest by punishing violations of the gaming laws. During the saturnalia, which was a period of general licence, these games were permitted (*Martial*, iv. 14), and a like indulgence at other seasons was extended to old men both amongst the Greeks and Romans (*Eurip. Med.* 67; *Juv.* xiv. 4). Nor has this vice been confined to civilised nations, either in the ancient or the modern world; Tacitus (*De Mor. Ger.* c. 2) mentions its existence amongst our own barbarian forefathers, and it is known to prevail amongst many half-civilised and even savage tribes at the present day. In general, it is resorted to as a refuge against the depressing sensations of languor and vacancy, which the want of active exertion causes in the minds of those who have no inner life; and the classes most addicted to it in all countries are the idle, and mere men of business in their idle hours.

It is remarkable that in England, as in Rome, the ground on which gambling was first prohibited was, not its demoralising, but its effeminating influences on the community. The act 33 Henry VIII. c. 9 (1541) has in view the double object of 'maintaining artillery and debarring unlawful games.' By 'artillery' appears to be meant archery, and the act, reciting two others in the same reign, proceeds on the preamble, that the skill of the people in this martial art 'is sore decayed, and daily is like to be more and more diminished.' The cause of this degeneracy is stated to have been the practice among the people of 'many and sundry new and crafty games,' which not only diverted popular attention from the more manly and patriotic art of shooting with the bow, but gave rise to murders, robberies, and other felonies. The act then proceeds to make anxious provisions for the revival of the art of shooting with yew bows, and for the abolition of the said games—among which 'carding' is expressly mentioned—in any common house. On this act followed 16 Charles II. c. 7, and 9 Anne, c. 14, the latter of which declared that all bonds, or other securities given for money won at play, or money lent at the time to play with, should be utterly void, and all mortgages or encumbrances of lands made on the same consideration, should be made over to the use of the mortgager. This statute applied to Scotland, where the nullity was found to affect any one holding a bond or bill as trustee for the winner, but not onerous or *bond-fide* endorsers, without notice of the objection (*Bell's Com.* i. p. 28, Shaw's edition). Such continued to be the statute law till 1845, when there was passed the act 8 and 9 Vict. c. 109, which, though it repealed the obsolete provisions of 33 Henry VIII. and 16 Charles II. c. 7, entirely affirmed, and even extended the prohibitions of the former enactments against card-playing and other games in common houses, and other public places. By this statute, also, the common law of England was altered, and wagers, which, with some exceptions, had hitherto been considered legal contracts, were declared to be no longer exigible in a court of law. This prohibition, however, only applies to bets and wagers made on unlawful games. In Scotland, an opposite rule had been followed, the judges having held, irrespective of the character of the game, or of any statutory prohibition regarding it, that 'their proper functions were to enforce the rights of parties arising out of serious transactions, and not to pay regard to

sponsiones ludicrae.' The partial assimilation which has now been effected in this respect between the laws of the two countries, is one the desirableness of which had been pointed out by many eminent English judges, from the time of Lord Mansfield down to the passing of the act, and which was at last adopted in accordance with the report of a select committee of the House of Commons in 1844. By this statute, it is also provided that cheating at play shall be punished as obtaining money under false pretences. It also facilitates proceedings against common gaming-houses, by enacting that where other evidence is wanting, it shall be sufficient to prove that the house or other place is kept or used for playing at any unlawful game, and that a bank is there kept by one or more of the players exclusively of the others; or that the chances of any game played therein are not alike favourable to all the players, including among the players the manager or managers of the bank. In order to constitute the house a common gaming-house, it is not necessary to prove that any person found playing at any game was playing for any money, wager, or stake. The police may enter the house on the report of a superintendent, and the authority of a commissioner, without the necessity of an allegation of two householders; and if any cards, dice, balls, counters, tables, or other instruments of gaming be found in the house, or about the person of any of those who shall be found therein, such discovery shall be evidence against the establishment until the contrary be made to appear. Those who shall appear as witnesses, further, are protected from the consequences of having been engaged in unlawful gaming. This enactment does not, of course, apply to the playing of games in private houses merely for purposes of amusement, even though a small pecuniary stake should be added to enhance the interest of the players; but where, from the heaviness of the stakes, and the systematic and repeated character of the playing, there could be no question that the crime of gambling was being committed in point of fact, the mere circumstance of the house being in other respects a private one, would not protect the players from the statutory penalties. In addition to the discouragement given to gambling in Scotland by the rule that bets and money gained at play could not be recovered by an action, it was also prohibited by statute. The act 1621, c. 14, enacts that playing in taverns is prohibited under a pecuniary penalty for the first offence, and a loss of licence for the second. Playing in private houses is also forbidden, if the master of the house do not play. This act, Mr Bell says, is not in desuetude (*Com.* i. p. 28), and the act of Anne, c. 14, in so far as not repealed, also applies to Scotland.

In most of the states of Germany, gaming is allowed, and the extent to which it is practised at the German watering-places is well known. The princes of the petty states often derive a large portion of their revenue from the tenants of their gaming establishments, whose exclusive privileges they guarantee. Abstracts of the laws of different countries relating to gaming were prepared by J. M. Ludlow, Esq., and laid before the select committee of the House of Commons. They will be found in a condensed form in volume 3 of the *Political Dictionary of the Standard Library Cyclopædia*.

GAMBO'GE, or CAMBOGE, a gum-resin, used in medicine and the arts, brought from the East Indies, and believed to be the produce chiefly of *Cambogia gutta*, also known as *Hebradendron gambogioides*, a tree of the natural order *Guttifera*.

a native of Ceylon, Siam, Cambodia, &c. The gamboge-tree attains a height of forty feet, has smooth oval leaves, small polygamous flowers, and clustered succulent fruit. The fruit is about two inches in diameter, sweet and eatable, and is also much used as an ingredient in sauces. When the

precipitate of the respective gambogiates of copper and iron.

In doses of a drachm, or even less, G. acts as an acrid poison, causing extreme vomiting and purging, followed by fainting and death. In small doses of from one to three grains, combined with aloes and ginger or aromatic powder, it may be given in case of obstinate constipation, in cerebral affections (as apoplexy, or where there is an apoplectic tendency), in dropsy (especially if connected with hepatic obstruction), and as a remedy for tape-worm. The use of G. is objectionable when there is an irritable or inflammatory condition of the stomach or intestines, or a tendency to abortion; and it is not very often prescribed by orthodox practitioners.

G. is much used by painters to produce a beautiful yellow colour. It is also employed for staining wood, and for making a gold-coloured lacker for brass. It has a shelly fracture, is destitute of smell, and has an acrid taste. It burns with a dense smoke and many sparks.

GAME. Certain wild animals are selected by what are called the game-laws from all other animals, and protected, for the exclusive benefit of those on whose lands they are found. Game-laws of one kind or another exist in all modern countries, and in recent times the tendency seems everywhere to be to render them more stringent. In ancient times, our kings distinguished themselves by the severity of the forest laws, from which the modern game-laws are descended; but the crown has now little to do with game, except where certain ancient forests, parks, and free warrens are to be found, and these continue to this day to be privileged places in many respects. The game-laws of England, Ireland, and Scotland are still quite distinct, and though in the most material parts they agree, yet there are several peculiarities to be attended to. The English statutes on the subject now in force are the Game Act 1 and 2 Will. IV. c. 32, and its amendments, 5 and 6 Will. IV. c. 20, and 6 and 7 Will. IV. c. 65; the Night Poaching Act, 9 Geo. IV. c. 69, and its amendment, 7 and 8 Vict. c. 29; the Larceny Act, 24 and 25 Vict. c. 96; the Hares' Killing Act, 11 and 12 Vict. c. 29, and the Game Licences' Acts, 23 and 24 Vict. c. 90, and 2 and 3 Vict. c. 35. These, however, only constitute the statute law on the subject, and there is interwoven with them the common law, both of which require to be taken together. Our present space precludes our giving more than the substance of the leading doctrines on the subject.

Blackstone laid down the doctrine, that at common law the sole right of hunting and killing game belonged to the crown, and that the subject could only claim this right by tracing title to the crown. This doctrine has, however, been clearly shown to be erroneous, and Professor Christian was the first to point it out. It is now well settled that at common law the owner of the soil, or, if he has granted a lease without reserving the right, then the lessee or occupier, has the right to kill and catch every wild animal that comes on his lands. This is still the law, but the game-laws have made it necessary that the owner, or other person having the legal right, shall, before doing so, take out a game-licence—in other words, pay a tax to the state. Not only is a game-licence necessary in all cases, but there is a certain season, called the close season, during which it is unlawful for every person, whether having the legal right or not, to catch or kill game. Game is defined to include the following animals only—viz., hares, pheasants, partridges, grouse, heath-game, moor-game, black-game, and bustards. The close season applies only to the winged game, so that hares can be lawfully killed all the year

Gamboge (*Hebradendron gambogoides*):

a, back view of a male flower; b, side view of male flower; c, an anther, with its umbilicate lid.

bark of the tree is wounded, G. exudes as a thick viscid yellow juice, which hardens by exposure to the air. Another species of the same genus (*C. pictoria*) occurs in the Mysore, and is believed to produce G. of similar quality. The finest G. comes from Siam.—*American G.*, which is very similar, and used for the same purposes, is obtained from *Vernicia Guianensis*, a tree of the natural order *Hypericaceae*, a native of Mexico and Surinam.

G. occurs in commerce in three forms: 1. in rolls or solid cylinders; 2. in pipes or hollow cylinders; and 3. in cakes or amorphous masses. The first two kinds are the purest. Good G. contains about 70 per cent. of resin and 20 per cent. of gum, the remainder being made up of woody fibre, fecula, and moisture. On evaporating to dryness the ethereal texture of the pure gum-resin, we obtain a deep orange-coloured or cherry-red substance, to which the terms *gambogic* and *gambodic acid* have been applied. Its composition is represented by the formula $C_{14}H_{14}O_8$, according to Johnston (*Phil. Trans.* 1839).

As the detection of G. in quack medicines, &c., is occasionally of great medico-legal importance (death having often taken place in consequence of the administration of Morison's pills and similar preparations), we may mention the following simple mode of procedure. Digest one portion of the suspected substance in alcohol, and another in ether. In each case, if G. is present, we obtain an orange-coloured tincture. The ethereal tincture dropped in water yields, on the evaporation of the ether, a thin, bright-yellow film of gambogic acid, which is soluble in caustic potash. The alcoholic tincture dropped into water yields a bright, opaque, yellow emulsion, which becomes transparent, and of a deep red colour, on the addition of caustic potash. On the addition of acetate of lead to either of these solutions, we have a yellow precipitate of gambogiate of lead; similarly, sulphate of copper yields a brown, and the salts of iron a dark-brown

sound. But no game must be killed on Sundays or Christmas-day; to do so, subjects the offender to a penalty of £5. Though the above animals alone are game, the game acts also protect certain other animals—viz., woodcocks, snipes, quails, landrails, and conies; that is to say, any person illegally trespassing in pursuit of these may be fined £2. The eggs of game are also protected. In general, the game-laws consist merely of a net-work of penalties directed against those illegal trespassers, and these will be more properly stated under the head of POACHING (q. v.). Trespassers in the night-time, in pursuit of game, are punished more severely than those in the daytime; and when there are several persons acting together, exceeding five, the penalties are increased, and still more so when the poachers are armed with dangerous weapons, and use violence.

As between landlord and tenant, the general rule is, that, if there is no provision to the contrary in the lease, the tenant has the exclusive right to kill the game, and not the landlord; hence, the landlord, in order to preserve the right, must always introduce an express clause in the lease for his protection. When that is done, then the tenant may be punished like other persons for poaching. Formerly, it was attempted to protect lands against poachers by setting spring-guns and man-traps, and the English courts were inclined to hold this to be legal. But to put an end to all doubt, a statute was passed, and is now in force, which expressly prohibits spring-guns except to protect dwelling-houses (24 and 25 Vict. c. 100, s. 31).

In order to discountenance poaching, game is declared to be not a legal article of sale except by licensed game-dealers; this licence costs £2. The game-dealer can only buy his game from licensed sportsmen, and it is an offence for any of the public to buy game except from these licensed dealers, or to sell game without a licence; but sportsmen are not prohibited from making presents of game to any person.

As regards game-licences, there are now of two kinds: one is annual, and costs £3; the other lasts about half the year, and costs £2. A gamekeeper's licence costs £2. These licences are necessary, not merely to kill game, but also to kill deer, woodcocks, snipes, quails, landrails, and conies or rabbits. An exemption, however, exists, as regards hares and rabbits, when the owner or occupier kills these on his own enclosed ground, or directs another person to do so, in which case no licence is necessary; but this exemption only applies when the lands are enclosed or fenced, and the owner or occupier has otherwise the legal right to kill the hares and rabbits. No licence is required for merely hunting with staghounds, greyhounds, or beagles, or killing deer in one's own park. Moreover, attendants or friends going out with licensed sportsmen, provided these merely assist, and do not play a principal part, do not require a licence. But in all other cases it requires a licence, not only for killing, but for pursuing game, or even for lifting and taking away dead game from a highway or field. Assessed taxes must also be paid for dogs—viz., for each dog 12s. See on the foregoing subjects, Paterson's *Game-laws of the United Kingdom*.

The policy of the game-laws has often been questioned. Mr Bright obtained a committee of the House of Commons in 1845, who examined the subject. These laws are represented, on the one hand, to be far too stringent, to be badly administered by interested justices, and, lastly, to be opposed to the moral sentiments of the lower orders, who persist in treating such offences as venial, if not praiseworthy. On the other hand,

owners of land say that they are entitled to protection against trespassers, and this is the only way by which they can be protected.

In Scotland, several of the foregoing statutes, such as the Night Poaching Act and the Game Licences' Act, also apply. There is a similar act as to day-poaching—viz., 2 and 3 Will. IV. c. 68, and as to hares, 11 and 12 Vict. c. 30. The provisions in the English act as to game-dealers and the sale of game also apply. But in Scotland, not only a game-certificate, but a qualification, is requisite to enable a person to shoot, except he has the permission of a qualified person. So it is in Ireland, but not in England. In Scotland, the close season differs slightly from that of England, and so does the definition of game. The law as between landlord and tenant is also so far different, that the presumption is the reverse in Scotland; for if nothing is said in the lease, the right to the game belongs to the landlord, and not to the tenant. A tenant has also a right of action against the landlord for excessive preserving, if extraordinary injury is thereby done to his crops—a right which does not exist in England or Ireland. See Paterson's *Game-laws*, Irvine's *Game-laws*.

In Ireland, the law is nearly the same in substance with that of England; but there are distinct statutes and minor differences as to the qualification to kill game, as to the definition of game, of close-time, &c. See Paterson's *Game-laws*, Levinge's *Game-laws*.

GAMMA, GAMME, or GAMMUT, the name given to the system of musical notation invented by Guido, the first note of which he called by the Greek letter Gamma. Later, the whole scale got the name of Gamma, but it afterwards fell into disuse with Guido's Solmisation. In modern music, the term is applied to the scale or compass of wind instruments.

GAMMARUS, a genus of Crustacea of the section *Edriophthalma* (q. v.), and order Amphipoda, of which one species, *G. pulex*, is extremely common in springs and rivulets in Britain, particularly where decaying vegetable matter has accumulated. It generally keeps near the bottom; swims on its side, with a kind of jerking motion, and feeds on dead fishes or any other animal matter. It is sometimes called the Fresh-water Shrimp.

GAMBRUN. See GOMBRON.

GAND. See GHEHT.

GA'NDIA, a beautiful town of Spain, in the province of Valencia, and 34 miles south-south-east of the town of that name, stands on the left bank of the Alcoy, about two miles from the sea. It is well built, with streets regular and spacious; is surrounded with walls and towers, has numerous ecclesiastical edifices, and a magnificent ducal palace, adorned with gilding and azulejos or coloured tiles. Its gardens are fertile and luxuriant beyond description. It has manufactures of linen, woollen, and silken fabrics, and a trade in rice, hemp, silk, and timber. Pop. 6000.

GANDO. 1st, A kingdom or empire of Soudan, situated on both sides of the Niger. It is bounded on the north-west by the empire of Songhay, and on

the south vast by the empire of Sôkoto. It consists of the provinces of Western Kebbi, Maûri, Zabërma, Dëndina, parts of Gurma, Borgu, and Yoruba, Yaûri, and Nûpe. The country is fertile, and the vegetation in many places luxuriant. The principal productions are the yam, the date, and the banana. The inhabitants are of the Fulah (q. v.) race, and mostly Mohammedans. When Dr Barth visited G. in 1853, the monarch or sultan was Khalilu, nephew of the great reformer Imâm Othman (see FULAH). He is described by that traveller as a 'man without energy, and most inaccessible to a European and a Christian'—living, in fact, in a state of monkish seclusion, and employing a younger brother to 'keep up a certain show of imperial dignity.' It is not surprising that under such a ruler Dr Barth should find 'most of the provinces plunged into an abyss of anarchy.'—2d, GANDO, a city, and capital of the above kingdom, lies in a narrow valley, surrounded and commanded by hilly chains. 'It is intersected,' says Dr Barth, 'from north to south by the broad and shallow bed of a torrent, which exhibited fine pasture-grounds of fresh succulent herbage, while it was skirted on both sides by a dense border of luxuriant vegetation, which altogether is much richer in this place than either in Sôkoto, or Wurno, being surpassed only by the fine vegetable ornament of Kano.' The interior of the place is very pleasant and animated, and the inhabitants are industrious and successful in the manufacture of cotton cloth.

GANDOLFO. See CASTEL-GANDOLFO.

GANGA, or SAND-GROUSE (*Pterocles*), a genus of gallinaceous birds, of the family *Tetraonidae*, closely allied to grouse and ptarmigan, but distinguished by a pointed tail. The toes are not feathered. The species are natives chiefly of the warm parts of Asia and of Africa, and are most abundant in arid sandy plains. Two species, the Banded Sand-grouse (*P. arenarius*) and the Pin-tailed Sand-grouse (*P. setarius*), are found in the south of Europe. The latter species is very abundant on the arid plains of Persia. In Europe, it is found as far north as the south of France, chiefly in the sterile *Landes*. It is always to be seen in the markets of Madrid. The Banded Sand-grouse is abundant on the vast steppes of the south of Russia. The African species of this genus are often to be seen in large flocks near places to which they resort to drink.

GANGA SAGOR, a low swampy island at the mouth of the great western or holiest branch of the Ganges, particularly sacred in the estimation of the Hindus. Multitudes of pilgrims annually resort to it, at the time of full moon, in November and in January. Infanticide formerly took place to a vast extent at these festivals, but is now prohibited by the British government.

GANGES, a river prominent alike in the religion and in the geography of the East, divides, at least towards the sea, India in its largest sense into the two grand divisions of *Hither* and *Farther*. Its entire length is more than 1500 miles. Its general direction during the first half of its course is south-east; it then flows east through the plain of Bengal, as far as Rajmuhul, a distance of about 400 miles, after which it again proceeds in a south-eastern direction, and enters the sea through a multitudinous delta. For the purposes of detailed description, the stream, which exhibits such a great variety of phases in the different parts of its course may be conveniently broken down into five sections: (1) from its springs to Gangotri; (2) from Gangotri to Hurdwar; (3) from Hurdwar to Allahabad; (4) from Allahabad to Seebgunge, or the

head of the Delta; (5) from Seebgunge, or the head of the Delta, to the Bay of Bengal.

From its Springs to Gangotri.—The Bhageerettee, Bhagirathi, or Bhaghireti, generally regarded as the true G., rises in Gurhwal, near lat. 30° 54' N., and long. 79° 7' E., from a snow-field imbedded between three mountains of about 22,000 feet in height. The actual spot from which it is seen to issue is itself 13,800 feet above the sea. After a course of ten miles, throughout which the torrent is all but inaccessible, it reaches the temple of Gangotri, the first work of man on its banks, at an elevation of 10,300 feet, so as to have descended about 350 feet in a mile.—*From Gangotri to Hurdwar*.—After a run of seven miles, the stream is joined on the right by the Jahnuvi, considerably larger than itself, in lat. 31° 2' N. and long. 78° 54' E.; and the united waters, 13 miles further down, burst through the Himalaya Proper, in lat. 30° 59' N., and long. 78° 45' E. Still 90 miles lower, it receives the Aluknanda with a volume one half greater than its own, and here it first receives the name Ganges. A distance of 47 miles more carries the still rapid current down to Hurdwar, on the verge of the great plain of Hindustan, at an elevation of 1024 feet, shewing a descent of 9276 feet in 157 miles, or of nearly 60 feet in a mile.—*From Hurdwar to Allahabad*.—This portion of the river, measuring 488 miles, and averaging a fall of 22 inches in a mile, is beset almost throughout by shoals and rapids. It is navigable, however, for river-craft the whole way to Hurdwar, for passenger-steamers to within 100 miles of the mountains, and for loaded barges up to Cawnpore, which is 140 miles above Allahabad. This last-mentioned city stands at the confluence of the G. and the Jumna.—*From Allahabad to Seebgunge, or the head of the Delta*.—This, the longest of the five divisions of the stream, measures 563 miles in length, and has a fall of about five inches in a mile. Notwithstanding many shoals, it is practicable throughout, even in the driest season of the year, for vessels drawing fully 18 inches. About 270 miles below Allahabad, the G. is joined on the left by the Ghogra, having previously received the Gumti on the same side, and the Tons and the Kurumnassa on the right. About half-way between Allahabad and the Ghogra is the city of Benares. Between the Ghogra and Seebgunge, the principal affluents are the Sone on the right, and the Gunduk and the Coosy or Sun Kosi, on the left. Along this entire section, the G. varies largely both in breadth and in depth, according to the season of the year and the state of the water.—*From Seebgunge, or the head of the Delta, to the Bay of Bengal*.—Here the descent, along a line of 283 miles, averages about three inches in a mile. Hitherto swollen by its feeders, the G. now begins to send off branches, parting at Seebgunge with the Bhagrutti, and next, 70 miles further down, with the Jellinghi, at the town of the same name, which, after separate courses of about 120 miles each, unite to form the Hoogly of Calcutta. Below the point of departure of the Jellinghi, it throws out similar offsets, the Marabhanga, the Gorae, the Chundni, and the Kirtynassa. Meanwhile, this waste towards the right is in a great measure compensated by affluents on the left, more especially by various channels of the Brahmaputra—the two great net-works of waters intertwining themselves together in a manner too complex for delineation, and at last indenting a long line of coast with at least 20 estuaries. The mouth of the Hoogly, the most available of all the branches of the G. as the means of communicating with the outside world, is in lat. 21° 40' N., and long. 88° E. By it the largest

GANGES.

ships reach Diamond Harbour, while vessels of considerable burden ascend to Chandernagore. Between the Hoogly and the G., above the Delta, there are two routes. When the water is high, the Bhagrutti and the Jellinghi afford the requisite facilities; but in the dry season, the intercourse is maintained by the Sunderband or Sunderbans Passage, a circuitous course to the north-east, which opens into the Chundni.

As a whole, however, the G. is incapable of being definitely described. It varies not merely from season to season, but also from year to year. From year to year it exchanges old passages for new ones, more particularly in the alluvial basin of its lower sections. Even as far up as Futtehpore, immediately above Allahabad, this characteristic is remarkably exemplified. The river has in this part a bed of the average width of four miles, within the limits of which it changes its course annually, in the lapse of four or five years shifting from the one limit to the other. Between season and season, again, the fluctuations are still more conspicuous. To take Benares as an instance, the stream ranges, according to the time of the year, from 1400 feet to 3000 feet in breadth, and from 35 feet to 78 feet in depth. Lower down, the vicissitudes, without being more striking in themselves, produce more striking results. About the close of July, a considerable proportion of the Delta forms an inundation of more than 100 miles in diameter, presenting nothing to the eye but villages and trees, and craft of every sort. To prevent or mitigate this evil, expensive dams have been constructed, having collectively a length of above 1000 miles. The influence of the tides extends, at the dry season, a distance of 240 miles from the sea. The minimum quantity of water delivered per second has been estimated at 36,330 cubic feet, and the maximum at 494,208 cubic feet. Like all rivers that overflow their banks, the G. holds in suspension a large admixture of mud and sand—foreign elements eminently unfavourable to steam-navigation, as causing quick wear and decay of the cocks and valves of the engines. It has been computed that it delivers, on an average, annually into the sea 534,600,000 tons of solid matter.

Amongst the rivers which at the *classical* and the *Paurānic* period of India were held in peculiar sanctity by the nation, the G.—or, as it is called, the *Gangā* (feminine)—undoubtedly occupied the foremost rank. In the vedic poetry, it is but seldom mentioned; and whenever its name occurs, whether in the hymns of the *Rigveda* or the ritual text of the *Yajurveda*, no legendary fact or mythical narrative is connected with it. Nor does the law-book of Manu justify the conclusion that its author was acquainted with any of the myths which connect this river in the epic poems and in the *Purānas* with the Pantheon of India. The earliest, and by far the most poetical legend of the G., occurs in that master-piece of Sanscrit poetry, the *Rāmāyana*. We give its substance, because it explains the principal epithets by which this river is spoken of, or invoked, in ancient and modern Hindu poetry, and because it may be looked upon as the type of the many fables which refer to the purifying and supernatural properties of its waters. There lived, says the *Rāmāyana*, in Ayodhyā (the modern Oude), a king, by the name of Sagara, who had two wives, Kesini and Sumati; but they bore him no issue. He therefore repaired to the Himalaya; and after a hundred years' severe austerities, Bhṛigu, the saint, became favourable to his wishes, and granted him posterity. Kesini bore him a son, who was named Asamanjas, and Sumati brought forth a gourd, whence sprang

60,000 sons, who in time became as many heroes. Asamanjas, however, in growing up, was addicted to cruel practices, and was therefore banished by his father from the kingdom. His son was Anumat, who thus became heir to the throne of Ayodhyā. Now, it happened that Sagara resolved to perform a great horse-sacrifice; and in accordance with the sacred law, chose for this purpose a beautiful horse, which he confided to the care of Anumat. But while the latter was engaged in the initiatory rites of the sacrifice, a huge serpent emerged from the soil, and carried off the horse to the infernal regions. Thereupon, Sagara, being informed of the obstruction which had befallen his pious undertaking, ordered his 60,000 sons to recover the horse from the subterranean robber. These then set to work, digging the earth, and striking terror into all creation. Having explored, for many years, the infernal regions, they at last found the sacred horse grazing, and watched by a fiery saint, in whom they recognised the serpent, the cause of their troubles. Enraged, they attacked him; but the saint, who was no other being than Vishnu, at once reduced them to ashes. Waiting in vain for the return of his sons, Sagara sent his grandson, Anumat, in search of them and the sacred horse. Anumat went, and soon ascertained the fate of his relatives; but when—mindful of his duties—he wished to sprinkle consecrated water on their ashes, so as to enable their souls to rise to heaven, Garuda, the bird of Vishnu, and brother of Sumati, came in sight, and told Anumat that it was improper for him to use terrestrial water for such a libation, and that he ought to provide the water of the Gangā, the heavenly daughter of Himavat (the Himalaya). Anumat, bowing to the behest of the king of birds, went home with the horse to Sagara; and the sacrifice being achieved, Sagara strove to cause the descent of the Gangā, but all his devices remained fruitless; and after 30,000 years, he went to heaven. Nor was Anumat more successful in his attempt with the austerities he performed for the same purpose, nor his son Dwilpa, who, obeying the law of time, after 30,000 years, went to the heaven of Indra. Dwilpa had obtained a son, named Bhagratha. He, too, was eager to obtain the descent of the Gangā; and having completed a course of severe austerities, he obtained the favour of Brahman, who told him he would yield to his prayers, provided that Siva consented to receive the sacred river on his head, as the earth would be too feeble to bear its fall when coming from heaven. And now Bhagratha recommenced his penance, until Siva consented, and told the Gangā to descend from heaven. The river obeyed; but, enraged at his command, she assumed a form of immense size, and increased her celerity, thinking thus to carry him off to the infernal regions. Yet the god becoming aware of her intentions, caught and entangled her in his matted hair, out of which she could find no means of extricating herself though erring there for many years. Nor would she have been released, had not Bhagratha, by his renewed penance, appeased the god, who then allowed her to descend from his head in seven streams—Hārdini, Pāvini, and Nalini, which went eastwards; and Sitā, Suchakshus, and Sindhu, which went westwards, whilst the seventh stream followed Bhagratha wherever he proceeded. But it so happened that the king on his journey passed by the hermitage of an irascible saint whose name was Jahnū. The latter seeing the Gangā overflowing in her arrogance the precincts of his sacrificial spot, and destroying his sacred vessels, became impatient, and drank up all her waters; thereupon all the gods became terrified, and promised him that, in future,

GANGES CANAL—GANGOTRI.

the Ganga would pay him filial respect, and become his daughter, if he would restore her again to existence. Quieted by this promise, Jahnū then allowed her to flow out from his ear, and therefore she is still called Jāhnavī, or the daughter of Jahnū. But, because Bhagiratha, by dint of his exertions, enabled his ancestors, now sprinkled with the waters of the Ganga, to ascend to heaven, Brahman allowed him to consider her as his daughter, whence she is called Bhāgirathī. And she is also called the river of 'the three paths,' because her waters flow in heaven, on earth, and pervaded the subterranean regions.—Such is the account of the *Rāmāyana*, and its substance is repeated by the *Mahābhārata* and several of the *Purānas*, though they differ in the names of the streams formed in her descent by the Ganga, some (for instance, the *Vishnu- and Vāyu-Purāna*) restricting their number from seven to four, called by the *Vishnu-Purāna* Śītā, Alakānandā, Chakāhu, and Bhadrā. A further deviation from the original myth was caused by sectarian influence; for, whereas in the *Rāmāyana*, the Ganga springs from the Himavat (Himalaya), whose daughter, therefore, she is, and whereas Śiva plays the most prominent part in her descent to earth, the *Vishnu-Purāna* assigns her source to the nail of the great toe of Vishnu's left foot, and allows Śiva merely to receive one of her branches on his head. The following passage from this *Purāna* will shew the ideas of the Vishnuite sect on the history and the properties of this river: 'From that third region of the atmosphere, or seat of Vishnu, proceeds the stream that washes away all sin, the river Ganga, embrowned with the unguents of the nymphs of heaven, who have sported in her waters. Having her source in the nail of the great toe of Vishnu's left foot, Dhruva (Śiva) reverses her, and sustains her day and night devoutly on his head, and thence the seven Rishis practise the exercises of austerity in her waters, wreathing their braided locks with her waves. The orb of the moon, encompassed by her accumulated current, derives augmented lustre from her contact. Falling from on high, as she issues from the moon, she alights on the summit of Meru, and thence flows to the four quarters of the earth, for its purification. The Śītā, Alakānandā, Chakāhu, and Bhadrā, are four branches of but one river, divided according to the regions towards which it proceeds. The branch that is known as Alakānandā was borne affectionately by Śiva, upon his head, for more than a hundred years, and was the river which raised to heaven the sinful sons of Sagarā by washing their ashes. The offences of any man who bathes in this river are immediately expiated, and unprecedented virtue is engendered. Its waters, offered by sons to their ancestors in faith for three years, yield to the latter rarely attainable gratification. Men of the twice-born orders, who offer sacrifice in this river to the lord of sacrifice, Pumaśhottama, obtain whatever they desire, either here or in heaven. Saints who are purified from all evil by bathing in its waters, and whose minds are intent on Kesava (Vishnu), acquire thereby final liberation. This sacred stream, heard of, desired, seen, touched, bathed in, or hymned day by day, sanctifies all beings; and those who, even at a distance of a hundred leagues, exclaim "Gangā, Gangā," atone for the sins committed during three previous lives.' How far the belief expressed in the latter passage was carried at a period probably succeeding that of the composition of the *Vishnu-Purāna* may be seen from a legend which occurs in the *Kriyāyogastotra*, the sixth division of the *Padma-Purāna*. This *Purāna* relates that a king, Manobhadra, having grown old and weak, resolved upon dividing his kingdom between his

two sons. He therefore convoked a council of his ministers, when, of a sudden, a vulture and his mate flew into the hall, to the surprise of the whole assembly. Questioned about the purpose of their visit, they replied that, having witnessed the evil luck of the two princes in a former birth, they now came to rejoice in their happiness. The king's curiosity having been roused, the male vulture then said, that in the age called Dwāpara, the two princes had been two men of low caste, called Gara and Sangara, and when dead, were brought before Yama, the judge of the dead, who sentenced them to be thrown into a fearful hell. Their lives had indeed been faultless; no sin had been committed by them, but whenever they gave alms, they did not offer them to a Brāhmana, and thus robbing the latter of the property which otherwise would have come to him, they became candidates for hell. He, the vulture, had come to the same place, because, when being a noble Brāhmana, Sarvasa, he alighted his parents. Now the period of their sentence having expired, he was reborn as a member of the vulture tribe, which is living on the flesh of the dead, whereas they became a couple of locusts. Once, however, a hurricane arose, and threw the locusts into the Ganges; there they died; but having found their death in the water of the river which destroys all guilt, the servants of Vishnu came with heavenly chariots to conduct them to his town. Having stayed there up to the end of the third Kalpa, they were bidden by Brahman to enjoy themselves in the paradise of Indra; and after a certain time they were reborn in the family of Manobhadra, ultimately to rule his country. All the hymns addressed to the Ganges—and a remarkable one occurs in the same division of the *Padma-Purāna*—partly allude to the legends mentioned before, or to other feats of purification worked by the sacred water of this river. Its efficacy is deemed, however, greatest at the spot where the Ganges joins the Yamunā, or Jumna, at Allahabad, and—the latter river having previously received the Saraswatī below Delhi—where in reality the waters of the three sacred rivers meet. In some representations of Śiva, the Ganga is seen in his hair, and the river issuing from her mouth; she is also pictured, as Moor tells in the *Hindu Pantheon*, as part of the *Trident* or sacred triad of the rivers just named, when she is white, and bears the forehead mark of Śiva; on her right is Saraswatī, red, and with a roll of paper in her hand; on her left, Yamunā, as Lakshmi, the deity of this river, blue, and holding a golden jar. The whole group is riding on a fish; the fish, the clothing of the goddesses, and the glory encircling their heads, being of gold.—Gangā is also considered as the mother of the god of war. See KĀRTTKEYA.

GANGES CANAL, a modern imitation, in some measure, of the more ancient works of the kind on the Jumna (q. v.), has two main objects in view—the irrigating of the Doab, and the avoiding of the difficulties in the navigation of the river above Cawnpore. Extending, on the right of the Ganges, from Hurdwar to the city last mentioned, it measures, including its branches, 810 miles—350 for the trunk, and 460 for the offsets. In its course, it crosses the Solani on perhaps the most magnificent aqueduct in the world. This noble work, erected at a cost of £300,000, consists of fifteen arches, each having a span of 50 feet; while the piers, sunk 2½ feet below the bed of the stream, are protected on every side against the force of the current by ingeniously compacted masses of piles and stones.

GANGLION, in Anatomy. See BRAIN and NERVOUS SYSTEM.

GANGO'TRI, a temple erected on the highest

accessible spot on the Ganges (q. v.), about 10,000 feet above the level of the sea, stands on the right bank of the river, here called the Bhagirathi, about ten miles from its source. Immediately in front, the stream expands into a small bay, which is subdivided into pools, taking their names respectively from Brahma, Vishnu, and other gods of the native mythology. Though the water is specially sacred, and ablution peculiarly efficacious, yet, from various causes, the pilgrims are by no means numerous. Besides the length and ruggedness of the journey, and the difficulty of procuring subsistence by the way, there is no accommodation for visitors, the only dwelling-house in the locality being occupied by the officiating Brahmans. Superstition, however, has found a remedy in the exportation of flasks of the holy element, sealed by the attendant priests.

GANGRENE, the loss of vitality in a part of the living body, whether external or internal, the part becoming often, in the first instance, more or less red, hot, and painful, then livid, and finally dark and discoloured, black or olive-green, according to circumstances, and putrescent; after which a separation takes place gradually between the living and dead parts, and if the patient survive, the disorganised and lifeless texture is thrown off, and the part heals by the formation of a Cicatrix (q. v.) or scar, indicating the loss of substance. Gangrene is an occasional consequence of Inflammation (q. v.), but is often also determined by more specific causes, such as Typhus Fever or Erysipelas (q. v.); sometimes, also, by the action of poisons on the system, and not unfrequently by disease or obstruction of the arteries of a part. This last is especially the case in the form called senile gangrene. Gangrene admits only to a slight extent of medical treatment; but there is sometimes a necessity for surgical interference, to preserve a useful stump, or to arrest bleeding. Generally speaking, the strength must be maintained by a nourishing but not too stimulating diet, and the part carefully preserved from external injury, and from changes of temperature.

GANGWAY (Saxon, *gangweg*), the entrance to a ship. There is a gangway on each side, consisting of steps or cleats nailed to the planks of the side, up which, by aid of a rope, it is necessary to climb. When, however, a vessel is in harbour, a portable flight of steps, called an accommodation-ladder, is usually hoisted out, by which the ascent is sufficiently easy.

GAN-HWUY, or **NGAN-HOEE**, one of the five eastern provinces of China Proper. It is intersected by the Yang-tze-kiang, on which river its capital, Gan-king-foo, is situated. In the south-eastern parts of the province are some extensive tea-plantations, and it also produces rice, grain, and a limited quantity of silk. Pop. according to the census of 1812, 34,168,059; area, 48,461 square miles.

GANJA'M, a town in the sub-presidency of Madras, stands on the left bank of the Rosikoila, immediately above its entrance into the Bay of Bengal, in lat. 19° 23' N., and long. 85° 7' E. It was once the capital of the district of its own name, and was remarkable for its fine buildings. But in 1815, when the town was visited by deadly fevers and agues, all the public establishments were removed to Chisacole (q. v.); the fort and cantonments gradually fell into ruin, and the place sank into decay.

GANJAM, the district mentioned in the preceding article, lies on the north-west coast of the Bay of Bengal, immediately to the south of Cuttack, stretching in N. lat. from 16° 18' to 19° 52', and in E. long. from 83° 50' to 85° 15', and containing 6400

square miles, and 928,930 inhabitants. The chief products are rice, maize, sugar-canes, millet, pulse, oil-seeds, wax, gums, dye-stuffs, and arrowroot. On the northern boundary is the salt-lake Chilka, 42 miles long, 15 broad, and only 6 feet deep. The country does not offer a single haven to ships of any burden. Small vessels, however, may enter the Rosikoila.

GANJEH. See **ELIZABETPOL**.

GANNAT, a town of France, in the department of Allier, is pleasantly situated on the Andelot, a tributary of the Allier, amid hills covered with vines and timber trees, 34 miles south-south-west of Moulins. In former times, it was fortified by walls and ditches, the latter being supplied with water by the stream on which the town stands. G. has tanneries and breweries, and a trade in corn, wine, and cattle. Pop. 5055.

GANNET (*Sula*), a genus of web-footed birds, of the family *Pelecanidae*, having a long, strong, conical bill, the face and throat naked, the feet with four toes, three before and one behind, all united by the web. To this genus the Booby (q. v.) belongs. Another species is the **COMMON G.**, or **SOLAN GOOSE** (*S. Bassana*), a bird which breeds on

Common Gannet, or Solan Goose (*Sula Bassana*).

insular rocks in the northern seas, and migrates in winter to warmer and even tropical regions. The name *Solan* or *Soland* Goose is from *Solent*, an old name of the English Channel. The entire length of the G. is about three feet; its general colour milk-white, the crown and back of the head pale yellow, the quill-feathers of the wings black. The G. lays usually a single egg, of a chalky white colour; the young bird, when newly hatched, has a naked bluish-black skin, but soon becomes covered with a thick white down, so that it resembles a powder-puff, or a mass of cotton; and when the true feathers appear, they are black, with lines and spots of dull white, so that the plumage of the young is very unlike that of the mature bird. The G. is long-lived, and takes about four years to come to maturity. Its motions on land are very awkward; but it is a bird of very powerful wing and graceful flight. It extends its flight to great distances from the rocks which it inhabits, pursuing shoals chiefly of such fish as swim near the surface, particularly herring, pilchards, and others of the same family. The presence of a shoal of pilchards often becomes known to the Cornwall fishermen from the attendant gannets. The G. may often be seen sailing in

the air, when suddenly, seeing a fish, it falls, with unerring precision, perpendicularly upon it. Gannets are sometimes taken by means of a board with a fish fastened to its upper surface, made to float a little beneath the surface of the water, the force with which the bird falls being sufficient to drive its sharp bill through the board, from which it cannot draw it back. Lundy Isle, the Bass Rock, Ailesa, St Kilda, and Sulisterry, are the most celebrated British breeding-places of gannets. The number of gannets that annually visit the Bass Rock in the Firth of Forth is estimated at nearly twenty thousand. The young are killed chiefly for the sake of their feathers, which bring a good profit to the person who rents the rock. There, and in similar localities, they are to be seen in prodigious numbers, the air around the rock being filled with them, like bees around a hive, and the rock itself whitened by them and their accumulated excrements. Their nests are formed of sea-weeds and marine grasses. On Great Gannet Rock, near the coast of Labrador, they are described as placed in regular rows. From this rock, great numbers of gannets are taken to be cut into bait for the cod-fisheries. The G., during incubation, will often allow itself to be touched with a stick without rising from the nest. Its flesh is rank and oily, but edible; but that of the young baked, is eaten to a considerable extent in many places, and is even reckoned as a delicacy. The eggs are considered by many connoisseurs to be a decided delicacy. They are boiled for twenty minutes, and eaten cold, with vinegar, salt, and pepper. The voice of the G. is harsh, and the cries of the multitudinous birds, when disturbed at their breeding-places, are deafening.—A species of G. (*S. variegata*), extremely abundant in some parts of the southern hemisphere, is said to be the chief producer of guano.

GA'NOID FISHES, one of the four orders of fishes in the classification of Agassiz, characterised by ganoid scales—shining scales (Gr. *ganos*, splendour), covered with enamel, angular, either rhomboidal or polygonal. Ganoid scales are often

Various forms of Ganoid Scales :

large, thick, and bony; they are usually placed in oblique rows, and united to each other by a kind of hook at the anterior angle. Recent ganoid fishes do not form a natural group, but differ in very important parts of their organisation. Some of them have an osseous, some a cartilaginous skeleton. Recent ganoid fishes are, however, comparatively few; whereas, among fossil fishes, the ganoid type is extremely prevalent. The sturgeon is an example of a ganoid fish.

GA'NTLET, or **GAUNTLET** (Fr. *gant*, a glove), an iron glove, which formed part of the armour of knights and men-at-arms. The back of the hand was covered with plates jointed together, so as to permit the hand to close. Gantlets were introduced about the 13th century. They were frequently thrown down by way of challenge, like

gloves. They are frequently used in heraldry, the fact of their being for the right or left hand being expressed by the words 'dexter' or 'sinister.'

In the phrase 'to run the gantlet,' the word is probably a corruption for *ganglope* (from *gang*, a passage, and the root occurring in *e-lope*—*D. loopen*, Ger. *laufen*, to run). The German has *gassenlaufen* (lane-run), meaning a military punishment, which consists in making the culprit, naked to the waist, pass repeatedly through a lane formed of two rows of soldiers, each of whom gives him a stroke as he passes with a short stick or other similar weapon.

GANTUNG PASS, in lat. 31° 38' N., and long. 78° 47' E., leads eastward from Kunawar, a district of Bussahir in Hindustan, into Chinese Tartary. Its height is 18,295 feet above the sea, and it is overhung by a peak of its own name, about 3000 feet loftier. The place is unspeakably desolate and rugged. It is, of course, beset with perpetual snow, and being devoid of fuel, it is but little frequented. Gerard, one of the few travellers that have visited it, crossed it—and that in July—amid snow and sleet. One peculiarity in the scene, according to the traveller just mentioned, is that the whitened surface presents here and there dangerous pools of still water.

GANYMEDES, the cup-bearer of Zeus, was, according to Homer, the son of Tros, or, according to others, of Laomedon, Ilius, or Erichthonius. The most beautiful of mortals, he attracted the notice of the king of the gods, who despatched his eagle to carry him off to heaven, where he succeeded Hebe in the office above referred to. The Greeks believed that Zeus gave Tros a pair of divine horses as a compensation for kidnapping his boy, and comforted him at the same time by informing him that G. had become immortal and free from all earthly ills. At a later period, G. was identified with the divinity who presided over the sources of the Nile. The Greek astronomers likewise placed him among the stars, under the name of Aquarius (the water-bearer), in allusion to his celestial function. He was also a favourite subject of ancient art.

GAOL. See **PRISON**.

GAOL DELIVERY, **COMMISSION OF**, is one of the four commissions issued to judges of assize in England, under which they discharge their duties on circuit. See **ASSIZE**. Commission of gaol delivery empowers the judges to try and deliver every prisoner who shall be in the gaol when they arrive at the circuit town. It is directed to the judges, with whom are coupled the serjeants-at-law and Queen's counsel on the circuit, the clerk of assize and the associate. It constitutes the persons to whom it is directed the Queen's justices, and orders four, three, or two of them, of whom one must be a judge or serjeant, to proceed to try prisoners. It was anciently the custom to issue special writs of gaol delivery for each particular prisoner, which were called the writs *de bono et malo*; but these being found inconvenient and oppressive, a general commission for all the prisoners has long been established in their stead (Stephen, *Comm.* iv. 371). It is not incumbent on the commissioners to deliver all the prisoners in the gaol, but they cannot try any one who was not in custody or on bail at the opening of the commission. A commission of gaol delivery has power to order that the proceedings at any trial shall not be published till all the trials are finished. Violation of this order is contempt of court, and is punishable by fine and imprisonment. At common law, a commission of gaol delivery is suspended by the Court of Queen's Bench sitting in the same county; but by 25 Geo. III. c. 18, the session at Newgate of oyer and terminer and gaol delivery is not to be interrupted by the commencement

GAP—GARBLERS.

of term and sitting of the King's Bench at Westminster. By 4 and 5 Will. IV. c. 36, a special court has been created for London and the suburbs, called the Central Criminal Court (q. v.), for which a special commission of gaol delivery is issued.

GAP, a small town of France, capital of the department of Hautes Alpes, is pleasantly situated on the right bank of the Luie, about 50 miles south-east of Grenoble. It is approached through walnut avenues, and surrounded by slopes on which the vine flourishes at the height of 2558 feet above sea-level. When seen from a certain distance, the town has a picturesque appearance; but on a closer inspection, it is found to be merely a labyrinth of dirty, narrow, and ill-paved streets. The chief public building is the cathedral, with a mausoleum in marble of the Constable de Lesdiguières. The town has manufactures of coarse woollens, linens, agricultural implements, and leather. Pop. 5453.

G., the ancient *Vapincum*, was formerly capital of the district of Dauphiné, to which it gave the name of Gapençois. At the commencement of the 17th c., it is said to have had about 16,000 inhabitants. Since that period, however, it has steadily declined in size and importance. It was sacked, and almost wholly reduced to ashes, by Victor Amadeus of Savoy in 1692.

GAPES, a disease of gallinaceous birds, owing to the presence of a trematode worm (*Fasciola trachealis*) in the windpipe. This entozoon, allied to the *Flukes* (q. v.), is, however, a creature of very different

Fasciola Trachealis :

A, the whole worm; B, the upper extremity, magnified; a, the sucker at the end of its branch; b, the head, with mouth.

general form, being a red, wavy, cylindrical worm, tapering at the tail, and forking near the upper extremity, the branch which is sent off terminating in a sucker for adhesion, whilst the mouth terminates the principal trunk. The whole length seldom exceeds an inch. Twenty of these worms, of various sizes, have been found in the windpipe of a single chicken. Pheasants, partridges, &c., are also liable to be infested by them. They produce inflammation, and sometimes suffocation and death. A common remedy is to introduce into the bird's throat the end of a feather, well oiled, and to turn it round, so as to dislodge the worms, which are then either brought out by the feather, or coughed out by the bird. Another cure is to give a little Epsom salts mixed with the food. Urine is often used in the same way, and with similar efficacy.

GARANÇEUX is a term now applied to the rough preparation which was formerly called garancine—namely, the spent madder acted on by sulphuric acid, as mentioned under **GARANCINE**.

G'ARANCINE, a manufactured product of madder; hence its name, derived from the French *garance*. The discovery of the process for making this material is due to the French, and it has proved one of the most valuable additions to our dyeing materials that has been made during the present century.

It was first practically used in the dyeing establishment of Messrs Lagier and Thomas at Avignon, where it was introduced with the hope of turning the spent madder to account; but the rude manner in which it was prepared prevented it from becoming

generally used for a long time, and our ignorance of the organic chemistry of madder at first hindered its improvement. It was first prepared by drying and pulverising or grinding the spent madder which had been used in the ordinary processes of dyeing madder styles; this was then saturated with sulphuric acid, which was supposed to char the woody tissue, and destroy the *alizarine* and some other organic products of the madder, but to have no effect upon the purpurine, which was consequently available for fresh dyeing processes. Subsequent experience shewed these views to be wrong, and garancine is now prepared from pure ground madder-root which has not previously been used.

For this purpose, the ground madder is mixed with water, and left for a day, and then fresh water is added, and the whole drawn off. By this means, the sugar, and probably the whole of the rubian, another principle of the madder, are dissolved and removed. Sulphuric acid is then added, and the temperature raised to about 90° F. for some hours, after which it is well washed with cold water, strained, pressed, and dried, and afterwards ground. In this state, it has a fine chocolate-brown colour, and looks somewhat like ground coffee. The advantages of garancine over madder are, that it is more easily used, and the colours it gives are brighter and more intense, although not so permanent.

GARAY, JÁNOS, a distinguished Hungarian poet, was born at Szegazárd in 1812. G.'s poetical genius manifested itself from early boyhood; for it was noticed by his teachers, that whenever he had to make a school *pensum* of Latin verses, he would usually bring at the same time an elaborate Magyar version. His *Csatár* (the Warrior) was published in 1834, and from that moment till his death, G. was one of the most assiduous workmen in the field of Hungarian literature, being attached in succession to the editorial staffs of the *Regelői*, *Rajzolatok*, *Hírnök*, and *Jelenkor*. G.'s dramatic works are—*Csáb*, a tragedy in five acts (1835); *Arbocz*, a tragedy in five acts (1837); *Országh Ilona*, an historical drama in three acts (1837); *Utolsó Magyar Khan*, a tragedy in five acts; *Báthory Erzsébet*, an historical drama in five acts. The first complete edition of G.'s poetical works was published at Pesth in 1843. A collection of tales appeared under the title of *Tollrajzok* in 1845; and the historical legends of Hungary, under the title of *Árpádok*, in 1847. A new series of poetry, under the title *Balaton-i Kanyók*, was published in 1848. He died at Pesth, November 5, 1853. His last work was *Szent László*, a long historical poem in 12 cantos (2 vols., Erlau, 1850). A complete edition of his poems was published after his death by Franz Ney (Pesth, 1853); and a select number of them have been translated into German by Kertbeny (Pesth, 1854; 2d edit., Vienna, 1857).

GARB, or **GARBE** (Fr. *gerbe*, Ger. *garbe*), a sheaf of any kind of grain. A garb is frequently used in heraldry. If it is blazoned a garb simply, then wheat is understood; if any other kind of grain is intended, it must be mentioned—a g., 'a garb of oats.'

GARBLERS, **GARBLE** (Fr. *garber*, to make clean). To garble signifies to sever and divide the good and sufficient from the bad and insufficient. Garbles signify the dust or soil that is severed. By 1 Rich. III. it was provided that no bow-staves should be sold ungarbled; and by 12 Ed. IV. c. 2, it is enacted that bow-staves be searched and surveyed, and that such as be not good and sufficient be marked. 1 James I. c. 19 was passed to preserve the purity of drugs. By this statute, thirty-two kinds of drugs are specified as garbleable;

and it was declared that all these drugs, &c., were to be garbled and sealed by the garbler before sale, on pain of forfeiture of the same or the value thereof. Power was given to an officer, called the garbler, at all times of the day to enter into any shops, warehouses, or cellars, to view and search for such drugs and spices, and to garble and make clean the same. This statute was repealed by 6 Anne, c. 16; but a similar power to that exercised by the garblers is, by 55 Geo. III. c. 194, now reposed in the Apothecaries' Hall of London.

GARCIA, MANUEL, a well-known musical genius, was born at Seville, in Spain, in 1775. After acquiring a considerable reputation as a singer in Cadiz and Madrid, he went to Paris in 1808, where he obtained great success at the Italian Opera; and in 1811 proceeded to Italy, where he was received with equal favour in Turin, Rome, and Naples. From 1816 to 1824, he was constantly engaged as a singer, either in Paris or London. Subsequently, with a select operatic company, composed in part of members of his own family, he crossed the Atlantic, and visited New York and Mexico. On the road between Mexico and Vera Cruz, he was robbed of all his money; and after his return to Paris, he was compelled to open a class for singing, as his voice had become greatly impaired by age and fatigue. Many of G.'s pupils reached a high degree of excellence, but none equalled his eldest daughter Maria, afterwards Madame Malibran (q. v.). He was less successful as a composer, although several of his works, especially *El Poeta Calculista* and *El Califo di Bagdad*, were much admired. G. died at Paris in June 1832.—**PAULINE VIARDOT-GARCIA**, second daughter of Manuel, was born at Paris in 1821. She has also acquired a great reputation as an operatic singer.

GARCILASO, surnamed (by himself) the *Inca*, was born at Cuzco, Peru, in 1540. He was the son of Garcilaso de la Vega, who belonged to the same family as the poet of that name, and who was one of the conquerors of Peru. G.'s father married Elizabeth Palla, a princess of the race of the Incas, and niece of the famous Huayna Capac, the last emperor of Peru, and G., though a Spaniard and a Christian, was exceedingly proud of the royal blood which flowed in his mother's veins. At the age of 20 he proceeded to Spain, and never again visited America. During the greater portion of his life he lived at Cordova, where he died in 1616. His first work was a *History of Florida* (*La Florida del Ynca*, Lisbon, 1605). It contains an account of the conquest of the country by Fernando de Soto. In 1609 appeared the first, and in 1616, shortly before his death, the second part of his work, on the *History of Peru*, entitled *Comentarios Reales que tratan del Origen de los Incas de sus Leyes y Gobierno*. This work is valuable, not so much for any great historical talent which it betokens in the author, as on account of its being almost the only source of information which we possess concerning the ancient Peruvians. G. well understood his mother-tongue, and was thus enabled to correct the errors which other Spanish writers had fallen into from ignorance of the Peruvian language. G.'s *History of Peru* was translated into English by Sir Paul Rycaut (Lond., 1688); and into French (2 vols. Amsterdam, 1727).

GARCILASO DE LA VEGA, a Spanish soldier and poet, was born at Toledo, in 1500 or 1503. He early adopted the profession of arms, and gained a distinguished reputation for bravery in the wars carried on by the Emperor Charles V. against the French and Turks, but was mortally wounded while storming a castle near Fréjus, in the south of France, and died at Nice, November 1536, in the

thirty-third year of his age. G., though prematurely cut off, lived long enough to win immortality, and though he wrote little, he revolutionised the national poetic taste of his countrymen. For the short metre of the older romances and redondillas, he substituted the hendecasyllabic verse of the Italians. His pieces consist of only 37 sonnets, 5 canzoni, 2 elegies, 1 epistle, and 3 pastorals. Singular to say, they do not contain a trace of military ardour, but are inspired by a tender sweetness and melancholy which appear to have deeply affected his countrymen. 'His sonnets,' says Ticknor, in his *History of Spanish Literature*, 'were heard everywhere; his eclogues were acted like popular dramas. The greatest geniuses of his nation express for him a reverence they shew to none of his predecessors. Lope de Vega imitates him in every possible way; Cervantes praises him more than he does any other poet, and cites him oftener. And thus G. has come down to us enjoying a general admiration, such as is hardly given to any other Spanish poet, and to none that lived before his time.' The best of the numerous editions of G.'s poems is that by Azara (Madrid, 1766). They have also been translated into English by Wiffen (Lond. 1823).

GARCINIA. See MANGOSTEEN.

GARD, a department in the south of France, bounded on the E. by the river Rhone, is triangular in shape, its southern extremity reaching into the Mediterranean in a headland which has a coast-line of about ten miles. It has an area of 2291 square miles, and in 1856 a population of 419,697. One-third of the area is arable, one-third waste land, and the remainder occupied by forests, plantations, vineyards, and, on the coast, by extensive and unhealthy marshes. It is watered mainly by the Rhone, and by its tributaries, the Gard—from which the department has its name—and the Ceze. Of its surface, the north-west is occupied by a branch of the Cevennes; the remainder slopes toward the Rhone and the Mediterranean. The soil is in general dry, the best land occurring in the river-valleys. Coal is found in several places, and salt-works are extensively carried on in the south. The vine (which yields about 26,400,000 gallons of wine annually), the olive, and the mulberry are the principal products. The chief manufactures are silk, woollen, and cotton goods; hats, ribbons, gloves, &c. Wine is largely exported. The department is divided into the four arrondissements of Nîmes, Alais, Uzès, and Le Vigan; the chief town is Nîmes.

GARDA, **LAGO DI**, one of the most remarkable of the Alpine lakes, and the largest in Italy, was the Lacus Benacus of the Romans. Its modern name is derived from the small village of Garda, situated on its eastern shore, and containing 3000 inhabitants. G.'s chief tributary is the river Sarca, which rises from the glacier of Monte Adamo, but it also receives several smaller streams descending from the valleys of Ledro, Tavalo, and Vesta. The northern extremity of the lake enters the territory of Trent in the Italian Tyrol. On the E. it has the province of Verona; on the W., that of Brescia; very variable; the average generally exceeds 120 and on the S., that of Mantua. Its greatest length, from Riva to Peschiera, is 32 miles; and its breadth, from Desenzano to Garda, 10 miles. Its depth is feet; in the direction of Malleine, it reaches 700 and 800 feet; and its maximum, as yet ascertained, is 1900 English feet. The principal islands are Trimelone, Olivé, and St Pietro. The scenery is grand. Alpine spurs border the lake on both sides, and descend steeply to its shores, but contain within

GARDAIA—GARDE NATIONALE.

themselves also many beautiful and fertile valleys. The waters of this lake are remarkably clear, and abound in fish of various kinds. Owing to the extent of its surface, and the violent winds to which it is exposed, waves often rise on it to a considerable height, giving its waters the appearance of a rough sea. The only outlet is the river Mincio at Peschiera, which descends to Mantua, and discharges itself into the Po. The mild climate in the district of the lake, and the beauty of its vicinity, have caused its shores to be lined with beautiful villas. Especially attractive to the scholar is the neck of land called *Sermione* (the *Sirmio* of Catullus), where the remains of that poet's country-house are still traceable. Since the peace of Villafranca, Lake G. forms the barrier which separates Venetia from the kingdom of Italy.

GARDAIA, or **GHARDEIA**, an important trading town of Algeria, in the Sahara, chief town, and seat of the Djemmâa or elective council of the Republic of the Seven Cities of the Mزاب district, is situated amid savagely naked and rocky mountains, in lat. 32° 28' N. and long. 4° 38' E., 312 miles in direct line south-south-east of Algiers. It is fortified by an enclosing wall, surmounted by nine towers, and pierced by ten gates; contains six mosques, one remarkable for its size; and has a flourishing trade by means of caravans with Tunis, Algiers, Fez, Morocco, Sûdan, and Timbuctu, in slaves, dates, barley, pottery, provisions, oil, wool, cotton, indigo, leather, gold-dust, ivory, and all the varied raw produce of Central and Northern Africa. G. is surrounded by extensive orchards, irrigated from wells, some of which are 900 feet deep. In the vicinity are the ruins of a tower, supposed to have belonged to the Romans. The Mزاب republic or confederacy pays to the French an annual tribute of 30,000 francs, 14,000 francs of which are contributed by G. alone. In return for this, the French secure them from all wars and marauders, and open to them freely the markets of the Tell, or coast regions of Algeria. Pop. 13,000. See the *Great Sahara, Wanderings South of the Atlas Mountains*, by H. B. Tristram (London, 1860).

GARDANT, in Heraldry, is said of an animal which is represented full-faced, and looking forward. See **PASSANT-GARDANT**.

GARDE NATIONALE, the celebrated burgher defenders of order in Paris and certain other French towns, was for the first time introduced into Paris during the Revolution of 1789. It had existed for a long time previous in some of the French towns, having been at first employed to defend the rights and privileges of the city, and subsequently to guard the persons and property of the citizens. When, in July 1789, the entire lower orders of the capital rose and demanded arms, the leaders of the Revolution, sitting at the Hôtel de Ville, seized the opportunity to decree, without consulting the government, the formation of a national guard for Paris of 48,000 citizens, which, in the first instance, they named the *Parisian Militia*. Each electoral district was to enrol a battalion of 800 men, divided into four companies of 200 men each, 15 of these companies forming a legion. The officers of the battalions were to be elected by the privates; but the higher officers were named by the Committee. The device chosen as the badge of the service was of blue and red, the colours of the city, to which white, the colour of the army, was added, to denote the intimate union which should subsist between the defenders of national liberty and the military. Thus arose the celebrated tricolor, afterwards adopted as the national badge, and now borne in honour wherever the French name extends. On

the king consenting to the removal of the regular troops from Paris, Lafayette (q.v.) was named Commandant of the National Guard of the city. Ere many more days had elapsed, the friends of municipal freedom had organised themselves into burgher troops in every important town, and the National Guard had become a recognised institution of the whole kingdom, the entire number raised being not under 300,000. The force soon acquired an extraordinary degree of discipline and efficiency—in a great degree from the number of old soldiers who, having deserted the crown, were elected to commissions by the municipal troops.

Throughout 1789, the National Guard looked on supinely at the excesses of the democratic party in the provinces, and joined the mob in Paris during the atrocities of the 5th October; but, under Lafayette, better counsels prevailed, and the national army restored order, rescuing the royal family on the 11th of October. For some months after this time, the National Guard firmly withstood the more violent insurrectionists, who would have deluged the capital with blood; but irresolution and indecision marked their actions in August 1792, and they stood tamely by during the appalling massacres in the prisons. As the Revolution held its sanguinary course, the National Guard receded more and more from the moderate views which it had at first supported, until, in 1794, we find it among the most devoted adherents of Robespierre and his bloody triumvirate, ever ready to lend its aid in the execution of their merciless decrees. Later in the year, however, when the Reign of Terror stood balanced between power and death, the National Guard proved, under the command of Barras, faithful to the Convention, which had deposed Robespierre and his terrible colleagues. In 1795, the National Guard aided in the disarmament of the populace; the reign of the multitude ceased, and the force itself was thoroughly re-organised, all elements of internal turbulence being carefully excluded from its ranks. Under this constitution, none were eligible to serve as National Guards but citizens of substance, labourers and the lowest classes being deemed dangerous. Not many months after, so great was the reaction, that the corps had become quite royalist in its feelings, carrying their sympathies at length to open rebellion against the Convention; but they sustained an utter defeat from a small body of troops of the regular army, who, under Barras and Napoleon Bonaparte, defended the Convention. After this reverse, the National Guard ceased practically to exist. It is worthy of remark, however, that in 1794 the latter general had been offered the command of the National Guard by Robespierre, and had declined it: had he accepted, how different might have been the fate of Europe.

In 1806, on the eve of the great continental campaign, which he expected would denude France of its regular troops, Napoleon re-instituted the G. N., taking care, however, that no elective or democratic principles should pervade the body. By a decree of September 23, in which the whole empire was included, every man in good health was required to serve, between the ages of 21 and 60: the officers were to be named by the Emperor. The companies were localised among the villages and townships; ten companies formed a cohort, and several cohorts, according to the district, formed a legion. This force was maintained in succeeding years in discipline and efficiency; and in 1812, before the great Russian campaign, the Emperor placed a large portion of the National Guard on permanent duty. He reaped the advantages of this step when, in 1813, after the disastrous issue of that year's warfare, he

GARDELEGEN—GARDENING.

found 100,000 well-drilled steady troops ready to replace his lost veterans, and fill some of the vacancies in the ranks. In 1814—when advancing to meet the allies, he parted from his empress and his son, the little king of Rome, for the last time—Napoleon solemnly committed them to the protection of the National Guard of Paris. After the Bourbon restoration, the National Guard continued an important body in the state until 1827, when, its attitude becoming insubordinate, Charles X. dissolved it, but neglected to *disarm* the members. Enraged at this slight, these men were among his most formidable opponents at the revolution of 1830. Under Louis Philippe, in that year, the G. N. was re-established throughout France, Lafayette being appointed to the command-in-chief, a post, however, from which he was removed shortly afterwards, as his power became dangerously great. In 1831, the National Guard of Lyon was implicated in the insurrection there; and in the following year, a considerable portion of the urban legions of Paris took part in the sanguinary disturbances of the Quartier St Meri, in which, however, they were overcome by the firmness and fidelity of the suburban legions of the *banlieu*. Feeling its power over the Citizen King of its own creation, the National Guard verged more and more towards republican principles, until, in the critical moments of the reform insurrection of 1848, the guard of the capital deserted from Louis Philippe to the revolutionists, and so put an end to the Orleans dynasty. In the troubles of the spring and summer of 1848, the G. N.—a few legions, subsequently dissolved, excepted—steadfastly supported order, and opposed the Socialists. On the election of Louis Napoleon to the presidency, he found it necessary to dissolve the Guards in 153 communes; and he re-organised the remainder on a footing to insure the absence of Socialistic views.

By an ordinance of June 1851, the National Guard was placed nearly on the footing of Louis Philippe's reign; but by a subsequent decree of 1852, which still holds, the entire force was dissolved, and reformed on a more military basis, in certain departments only. Now, all officers are named by the emperor, by whom alone the formation of special corps can be sanctioned. In revolutionary times, a national guard has been established in other countries also, and still continues to exist in Belgium and Italy. In the southern portion of the latter kingdom, the services of the national guard are at present (1862) in frequent requisition in the cause of order.

GARDELEGEN, a small town of Prussian Saxony, is situated about 30 miles north-north-west of Magdeburg, on the Milde. It has manufactures of leather, several mills and distilleries, and five annual fairs. Pop. 5402. G. is very old. Tradition says that in ancient times it was called Isenburg (*Castrum Isidis*), from being a sanctuary of the goddess Isis, and that it was destroyed by the Franks. Be this as it may, it was certainly destroyed by a Duke Dervan in 633 A. D., and rebuilt about 924. Subsequently, for a long period, it was the seat of princely markgrafs, who were called Counts of Gardelegen. Until 1478, it remained a free town.

GARDE'NIA, a genus of trees and shrubs, of the natural order *Cinchonaceæ*, natives of tropical and sub-tropical countries, many of which are now favourites in our green-houses and hothouses, on account of their beautiful and fragrant flowers. Some of them are hardy enough to endure the open air in summer. The corolla is funnel-shaped, or approaching to salver-shaped, the tube much longer

than the calyx; the fruit is a berry crowned with the calyx. *G. florida* and *G. radicans* are among the species best known in Britain, and bear the name of Cape Jasmine, but are natives of Japan. The fruit of the former, which is about the size of a pigeon's egg and orange-coloured, is sold in the shops of China and Japan for dyeing silks yellow. A beautiful yellow resin exudes from wounds in the bark of *G. arborea* and *G. gummifera*, Indian species. The wood of *G. Thunbergii* and *G. Rothmannia* is very hard, and is used for agricultural implements, wheel axles, &c., at the Cape of Good Hope. Both of these species are known in Britain as esteemed hothouse plants.

GARDENING, or **HORTICULTURE**, differs from agriculture in the comparatively small extent of ground used, the much greater variety of productions sought from it, and, consequently, also to no small extent in the manner of cultivation. The different ordinary productions of the garden are usually classed under the three heads of *Flowers*, *Fruits*, and *Culinary Vegetables*, concerning which see FLOWER-GARDEN, FRUITS, and KITCHEN-GARDEN. In large gardens, these departments are kept very distinct, particularly the first and last of them; but in small gardens they are generally more or less combined.

Where circumstances permit a choice of situation, a garden ought to be as fully as possible exposed to the rays of the sun, and in the northern parts of the world a gentle slope to the south, south-east, or south-west is even preferable to a perfect level. But a slope in the opposite directions is by all means to be avoided. The form of a garden, unless where some peculiarity of situation determines it otherwise, is usually a parallelogram; and it is considered desirable, at least in the case of a walled garden, that it should be longer from east to west than from north to south, in order to have as much as possible of the best exposure of wall for fruit-trees. This is also sometimes increased by the enclosure within a fence of some other kind, of a piece of ground called a *slip*, exterior to the wall. A wall, either of brick or stone, is the best enclosure for a garden; brick being preferable on account of its more perfect adaptation to fruit-trees (see WALL-TREES); but where this is deemed too expensive, hedges of thorn, holly, &c., are resorted to. Hedges afford good shelter from winds, but have the disadvantages of harbouring birds and snails to an inconvenient degree, and of withdrawing to their own support much of the strength of the adjacent soil. The garden, if in the form of a parallelogram, is usually divided into smaller parallelograms; a large garden, in the first instance, by cross-walls, smaller gardens at once by *walks*, and the *plots* thus formed are, if necessary, broken up by paths into smaller plots or *beds* for different kinds of plants. The paths within the plots are made by mere treading with the foot, when the ground has been newly dug, and are intended only for a single season; the walks are permanent, and are carefully made, usually by throwing out the earth to the depth of at least a few inches, and supplying its place with stones, cinders, broken bricks, slag from furnaces, or the like—whatever, in fact, is least likely to afford nutriment to plants—the surface being covered with gravel, which is kept clear of weeds by frequent stirring with the hoe or Dutch hoe. The walks are seldom less than five feet in width. The ground occupied by them is still useful for the nourishment of plants, and particularly of trees or shrubs, growing near them. They have generally Edgings (q.v.) to separate them neatly from the adjoining cultivated ground; and in damp situations, it is thought desirable to have them as much elevated as the

GARDENING.

centre as is consistent with comfort in walking on them.

The soil of a garden is often prepared with a degree of care which is impossible in regard to a farm. A deep, rich, and easily penetrable soil is desirable; and where the immediate expense is not much regarded, the soil of a garden is sometimes almost entirely artificial; more generally, means are used for ameliorating the original soil. Of these means, one of the most important is *trenching*, by which the soil is deepened, and it is desirable that the soil of a garden should be at least three feet deep. The proper depth of trenching, however, depends on the original depth of the soil and the nature of the subsoil; where the soil is pretty uniform to a considerable depth, the deepest trenching is advantageous; and the available soil may often be deepened by incorporating a portion of the subsoil with it, but if too much of a subsoil unsuited for vegetation is at once thrown up by trenching, it may communicate its own barrenness for years to the soil, ere it is mellowed by exposure to the air, manures, and the processes of cultivation. A stiff clay soil is very unsuitable for many of the crops required in a garden, and ought to be mixed with as much sand and vegetable matters as can easily be procured, both at the formation of the garden and afterwards. It is of course necessary, in all cases, that a garden be thoroughly drained; it is also of great consequence to have the means of irrigation, or at least of abundant watering, which, even where the climate is generally moist, greatly tends to increase the produce in dry seasons, and is almost always necessary to the perfection of certain crops. Indeed, if water can be obtained to form a small pond, or to pass through the garden as a rivulet, it may not only be turned to account for purposes of ornament, but also of utility, in the cultivation of many plants which cannot be successfully cultivated otherwise. This use of water is far from being so common as it might be in British gardens; even a cranberry-plot, although a pleasant thing and of easy attainment, being seldom thought of; the Chinese are better acquainted with it, and cultivate aquatic plants to an extent that has never been equalled amongst any other people.

A liberal supply of manure is necessary for a garden; the kinds of manure must be accommodated to the soil and to the different plants, and must often also depend in part on other circumstances. Care must be taken not to overdo with guano, or indeed with strong manure of any kind, by which plants might be killed rather than nourished. Farm-yard or stable-yard manure ought in general to be subjected to a process of decomposition in heaps before being used; and great advantage is derived from mixing it with other substances to form Composts (q. v.). Nor ought any of the weeds and other refuse vegetable produce of the garden to be thrown away or dissipated in smoke, but all should be gathered into some corner appropriated to the purpose, there to decompose and form a heap of vegetable mould, which is for many purposes one of the best manures that can be used. Peat is, in some soils and for some plants, a very useful manure or ingredient in the formation of composts.

A garden ought to be *delved* or dug with the spade in the end of autumn, except where the presence of a crop prevents, the ground being left very rough, to expose the soil as much as possible to the influences of the weather. When the crops are planted in spring, a very slight stirring of the surface is all that is required. The usefulness of a garden, however, is much increased by making a considerable part of it produce crops even during

winter. Greens of various kinds are commonly obtained from the garden during winter, even in the northern parts of Britain; the variety of winter crops in the southern parts is greater; but nowhere is a system of constant cropping so thoroughly maintained as in the market-gardens around London. Of course, constant cropping requires frequent and abundant manuring; and care is taken that each crop is succeeded by one of a completely different kind, a rule which is indeed always, as far as possible, to be observed both in horticulture and agriculture.

In laying out large gardens, fruit-trees trained on espaliers are not unfrequently planted around the borders of plots; in smaller gardens, gooseberry and currant bushes generally occupy this situation, often in addition to a plot entirely devoted to these bushes. Fruit-trees are often also planted as standards in the plots devoted to culinary vegetables. The productiveness of a garden may certainly thus be increased, as ground duly manured will yield a greater return of different kinds of produce than of one kind, whilst the owner has the additional pleasure of the greater variety; but it is to be remembered that the roots of trees and bushes spread a long way through the soil, and render it less suitable for many crops.

The implements most necessary in gardening are the spade, fork, rake, hoe, Dutch hoe, garden-line, wheelbarrow, pruning-knife, and watering-can.

The practice of gardening, of course, varies much in different countries, on account of the difference of climate, although some of its rules are of universal application. Of the history of gardening, little needs to be said. We know little of the gardening of the most ancient nations, except that it was practised, both for the sake of the produce and for pleasure, in all the seats of civilisation; and that the Greeks borrowed their methods of gardening from the Persians, the Romans in their turn copying from the Greeks. Of the gardening of the Romans, some account has been transmitted to us, from which we know that they had attained to no small proficiency in it. During the middle ages, gardening continued to be sedulously prosecuted in all the more civilised parts of Europe; Charlemagne enacted laws which contributed much to its promotion; and even in comparatively barbarous regions it was carried to great perfection by the monks, traces of whose skill and diligence are still to be seen in the vicinity of many a ruined monastery. The practice long prevailed of forming gardens, if situated on a slope, into terraces, and many a fine example of this kind of garden still remains at old country-seats. In a few places, also, may be seen remaining specimens of the clipped hedges and fantastically clipped trees and bushes, which, until last century, seem to have been thought the chief ornaments of a garden; other puerile conceits being often associated with them, some of which are not yet entirely exploded, although a green bush in its natural form is universally regarded as more beautiful than one made to grow into the shape of a vase or of a peacock. But the history of taste in gardening accords with the history of taste in laying out parks and pleasure-grounds, concerning which, see LANDSCAPE-GARDENING.

The market-gardening of the neighbourhood of London is on a scale proportionate to the greatness and wealth of the city; large fields, instead of little plots, are devoted to one kind of crop, and as an illustration it may be mentioned, that from one garden alone 200,000 gherkins (young cucumbers for pickling) have been sent to market in a single day. At Mitcham, near London, and at a few other places in England, medicinal plants are largely cultivated.

Nurseries are gardens devoted to the raising of young plants, both trees and some kinds of culinary herbs, and of garden-seeds.

The cultivation of the more important garden-plants is noticed under their several heads. See also GRAFTING, GREEN-HOUSE, HOTHOUSE, HOTBED, STOVE, &c.

GARDES SUISSES, a celebrated corps in the French army, constituted 'Gardes' by royal decree in 1616. They comprised upwards of 2000 men, were always unswerving in their fidelity to the Bourbon kings, and are chiefly remarkable for their heroic end. On the 10th August 1792, they withstood the Parisian revolutionary mob, and defended the palace of the Louvre till almost every man was cut down. During the resistance they offered, the royal family was enabled to escape to such shelter as the National Assembly afforded.

GARDE-VISURE, the heraldic term used for what is commonly called the visor, or front part of the helmet, used for the defence of the face and eyes.

GA'RDINER, a city of the United States, North America, is situated in the south-west of the state of Maine, on the right bank of the Kennebec, seven miles below Augusta. It has numerous saw, paper, and other mills; has tanneries, machine-shops, a foundry, a woollen factory, and a pottery. G. is at the head of the ship-navigation of the Kennebec, and 6000 tons of shipping are owned here. Pop. (1850) 6486, but since the recent incorporation of part of the territory of G. with other townships, its population has decreased.

GARDINER, STEPHEN, a celebrated English prelate and statesman, the illegitimate son of Dr Lionel Woodville, Bishop of Salisbury, brother of Elizabeth Grey, queen of Edward IV., was born at Bury St Edmunds, Suffolk, in 1483. He studied at Trinity Hall, Cambridge, and in 1520 became master of his Hall. Soon after, through the patronage of the Duke of Norfolk, he was introduced to Cardinal Wolsey, who made him his secretary. In this capacity he acquired the confidence and favour of Henry VIII., and from his knowledge of the civil and canon law, was sent to Rome in 1527, to conduct the negotiation with the pope for the king's divorce from Catharine of Aragon. He was then usually called Dr Stephens. His exertions were unsuccessful; but having rendered services at the papal court to the Bishop of Norwich, he was by him afterwards appointed Archdeacon of Norfolk, while he promoted Wolsey's interests as a candidate for the pontificate. On his return, he was made secretary of state, and in the spring of 1531 was advanced to the archdeaconry of Leicester. In November of the same year, he was installed Bishop of Winchester. Notwithstanding his allegiance to the pope, he warmly supported the king's supremacy, and wrote a treatise in defence of it, entitled *De Vera Obedientia*. He was sent on embassies to France and Germany, and invariably opposed all measures tending to a religious reformation in England. He had a principal hand in the downfall and execution of Thomas Cromwell, in 1540, and he drew up an impeachment of heresy against Henry's last queen, Catharine Parr; but in a personal interview with Henry she re-established herself in the king's favour, and G. fell into disgrace. At the accession of Edward VI., January 28, 1547, for refusing to comply with the Reformed doctrines, he was committed to the Fleet prison, but released in the following December. In 1548, he was again seized, and committed to the Tower, and on his refusal to sign certain articles submitted to him, was deprived of his bishopric. When Mary ascended the throne in 1553, he was set at liberty, restored to his see, and appointed lord chancellor and first

minister of state. He took the lead in all the bitter persecutions of the Protestants during Mary's reign, and is charged with great caprice and extreme cruelty; but Dr Maitland shews that many of the statements regarding G. are gross misrepresentations, and that in very many instances the parties brought before his court were arraigned for treason or sedition, rather than for heresy; and Roger Ascham freely confesses that G. interposed to protect him when summoned by the council on a charge of heterodoxy. The management of the queen's marriage with Philip of Spain was intrusted to him, and he officiated at their nuptials. He died November 12, 1555. A treatise, entitled *Necessary Doctrine of a Christian Man*, printed in 1543, is said to have been the joint production of G. and Cranmer. G.'s character has been the subject of much criticism; but it can scarcely be doubted that he was a zealous, though not a spiritually minded, ecclesiastic. His devotion was that of an out-and-out partisan; but it was nevertheless real, after its fashion, for G. would have given his life to advance the cause which had commanded his sympathies and his support.

GARDINER, COLONEL JAMES, son of Captain Patrick Gardiner, was born at Carriden, in Linlithgowshire, January 11, 1688, and when only 14 years old, obtained a commission in a Scots regiment in the Dutch service. He afterwards entered the English army, and was severely wounded at the battle of Ramilies in 1706. G. fought with great distinction in all the other battles of Marlborough. In 1714—1715, he was made captain-lieutenant in a regiment of dragoons. Some time after, he gave a conspicuous proof of his courage, when, along with eleven other daring fellows (eight of whom were killed), he fired the barricades of the Highlanders at Preston. From an early period, G. was noted for his licentiousness, which was so marked, that ordinary officers, making no pretensions to religion, rather shunned his society, for fear of being corrupted; yet his constitution enabled him to pursue his vicious courses with apparent impunity, and in consequence of his continual gaiety and good health, he was known as 'the happy rake.' But in the year 1719, he suddenly became the subject of profound religious impressions. The circumstances, as narrated by Dr Doddridge (who had them from the hero himself), contain much that is marvellous, supernatural, and exceedingly improbable. Doddridge himself is hardly satisfied with G.'s account, and hints at the possibility of the whole being a dream, instead of a 'visible representation of the Lord Jesus Christ upon the cross, surrounded on all sides with a glory,' &c. He also mentions that G. 'did not seem very confident' whether the voice which came to him was really 'an audible voice, or only a strong impression on his mind equally striking.' Considerable doubt has recently been cast on the whole story by the publication of the *Autobiography of Dr Alexander Carlyle*, edited by John Hill Burton (Edin. Blackwood and Sons, 1860), in which Carlyle denies altogether the truth of Doddridge's version of the story, at least of the supernatural portion of it. The attendant circumstances, however, are of little moment one way or another; the great fact is the conversion of the brave but wicked soldier into a pious and excellent Christian, and regarding this there has never been any doubt. In 1724, G. was raised to the rank of major, and in 1726 he married Lady Francis Erskine, daughter of the fourth Earl of Buchan, by whom he had 13 children, only five of whom survived him. In 1730, he became lieutenant-colonel of dragoons, and in 1743 colonel of a new regiment of dragoons. He was killed at the battle

of Prestonpans, September 21, 1745; and the spot on which he fell is marked by a monument. The *Life of Colonel Gardiner*, written by Dr Doddridge, is a favourite volume with the more religious portion of the public.

GARESSIO, a town in the north of Italy, in the province of Mondovì, and 17 miles south-east of the town of that name, stands on the left bank of the river Tanaro. Tradition assigns to G. an antiquity which seems confirmed by the numerous Latin inscriptions and remains found in its neighbourhood; but owing to the many wars by which it has been devastated, its authentic archives have been entirely lost. Many varieties of marble are quarried here, especially the species known as Pernigliana. Pop. 6200.

GAR-FISH (*Selene*), a genus of fishes of the family *Scomberesocidae*, having the body greatly elongated and covered with minute scales. They are remarkable for the green colour of their bones. The flesh is wholesome, and is often used as food. One species only, the Common G. (*S. vulgaris*),

Gar-fish (*Selene vulgaris*).

occurs in the British seas. It is sometimes called Greenbone, Goreball, and Mackerel-guida, receiving the last name because it visits the coasts just before the mackerel, coming, in fact, from the deep to the more shallow water for the same reason, to deposit its spawn. It is usually about two feet in length; the tail is forked; the pectoral and ventral fins are small; the upper part of the head and back is of a dark greenish-blue; the cheeks and gill covers, the sides and the belly, are silvery white, the dorsal fin and tail are greenish-brown, the other fins white. The G. is a very lively fish; it swims near the surface of the water, and not unfrequently springs out of it. It is brought to the London market in considerable quantities. The flesh has a flavour somewhat like that of mackerel. Some of the species of G., in other parts of the world, attain a much larger size. Other species are fresh-water fishes of warm climates, as India and Guiana.

GARGANEY (*Anas querquedula* or *Querquedula*

wild duck, nor even as the widgeon; a rare British bird, more common in the south of Europe, found also in the north of Africa, and in Asia, at least as far to the east as Calcutta. The male G. is a beautiful bird; the prevailing colour dark brown, finely varied on the cheeks and neck, with short hair-like lines of white; the speculum grayish-green, margined with white; a conspicuous white streak over each eye, extending to the neck. The female is smaller than the male, the colours more dull, and the white streak obscure. The G. is very much esteemed for the table.

GARGANO (anc. *Garganus*), a group of mountains in the province of Capitanata, Naples, forming a peninsula, which stretches eastward for about 20 miles into the Adriatic Sea. The group is composed of three chains of mountains, one of which turns to the north-east, the other to the south, and the third to the west. Its greatest length is 48 miles, and its extreme breadth 24, the circumference being about 120 miles. The southern chain is bleak, sterile, and rocky, broken up into deep valleys, gorges, and ravines. The northern side, on the contrary, is entirely covered with woods, pastures, olives, pines, orange and lemon trees; and the valleys on this side are lovely and fertile, especially those of Rodi, Ischitella, Vico, and Stignano. Owing to the great abundance of aromatic plants which grow among the rocks of the mountains, G. is still as famous for its honey as in the time of Horace, who sings its praise. Monte St Angelo, one of the Gargano chain, is famous for the sanctuary dedicated to St Michael in the year 492, in consequence of a legendary appearance of the saint to St Lorenzo, Archbishop of Sipontum. An annual festival of St Michael is celebrated at this shrine, when crowds of pilgrims flock to the mountain, and increase greatly its picturesque effect by their gay and varied costumes. Mount G. possesses extensive alabaster quarries, which as yet have never been efficiently worked.

G'ARGARA, or **GARGARUS**. See **IDA**.

G'ARGLE, or **G'ARGARISM**, a class of medicines intended to be churned about in the mouth and throat, with a view of cleansing the parts when affected with discharges from ulcers; or of acting as Astringents (q. v.) or Stimulants (q. v.), in relaxed sore throat. The best gargles are composed of vinegar or hydrochloric acid largely diluted; of chlorine water or Condy's disinfecting liquor in putrescent cases; of port-wine, alum, and capsicum (cayenne pepper), when a stimulating effect is required; of tannin or oak-bark decoction with alum or borax, in case a pure astringent is needed. Gargles are very useful in the later stages of sore throat, in almost all its varieties.

G'ARGOYLE, a projecting spout, leading the water from the roof-gutters of buildings. Gargoyles of various forms have been used in almost all styles of architecture, but were peculiarly developed in connection with Gothic architecture. In some of the larger mediæval buildings, where the height of the walls is considerable, the gargoyles have to project very far, in order to fulfil their duty of throwing the rain off the walls, and are in such cases of a large size. The gargoyles of French buildings have usually great prominence, much more than in England. Some gargoyles are small and plain, others large and ornamental, according to their various positions. They are carved into all conceivable forms—angelic, human, and of the lower orders; and as in fountains, the water is generally spouted through the mouth. In late castellated buildings, they frequently assume the form of small cannons

Garganey, or Summer Teal (*Anas querquedula*).

dris), a species of duck or teal, considerably larger than the common teal, although not so large as the

projecting from the parapet. In modern times, the use of leaden pipes to convey away the water from

GARGOYLES.

St Stephen's, Vienna.

St Alkmunds Church, Derby; Horsley Church, Derbyshire; circa 1450.

roofs has almost entirely superseded the use of gargoyles.

GARIBALDI, GIUSEPPE, was born at Nice, 22d July 1807, of respectable parents. His father, the owner of a trading vessel, having been engaged all his life in maritime pursuits, young G. soon acquired a strong predilection for the hazards of a seafaring life. With the permission of his father, he adopted the profession of a sailor, and made his first voyage to Odessa under the command of an able and experienced seaman, Captain Pesante. He subsequently visited Rome, Cagliari, Vado, Genoa, &c., with various commanders, and soon became a skilful and fearless mariner, distinguished by his prompt decision in action and imperturbable presence of mind. In 1830, he was himself in command of the brig *Notre Dame de Grâce*; and about this time his sentiments of patriotism seem to have gained increased intensity, owing to his intercourse with a fervid Italian patriot, a casual passenger on board his vessel. From 1833, his acquaintance with Mazzini and the leaders of the Italian liberal movement dates, and from that period his unquenchable hatred of despotism, and devotion to the service of universal freedom, exercised a predominant influence on all his actions, and ultimately became the single motive of his career. In 1834, having compromised himself by participating in a futile revolutionary outbreak at Genoa, he was compelled to save his life by flight; and after extreme hardship, succeeded in gaining French territory simultaneously with the publication in Italy of the sentence of his condemnation to death. G. now resumed his seafaring life, and after some unimportant voyages, sailed for South America. When Rosas, the dictator of Buenos Ayres, declared war against the republic of Uruguay, G. offered his services to the latter, and soon gave proof of so remarkable a talent for military leadership, that he was raised to the supreme command both of naval and military operations. In 1848, war having broken out between Austria and the liberals of Italy, G. hastened to

Europe. He bore an effective part in the whole of the Italian campaign, but especially distinguished himself at Rome by his resistance to the French forces, who during four weeks were successfully kept at bay, and repeatedly repulsed by the republican forces of Rome, under the direction of Garibaldi. Rome having at length succumbed to the immensely superior forces at the disposal of General Oudinot, G. marched forth from the city as the French poured in. After a retreat of unparalleled difficulty through districts densely occupied by Austrian forces, G., accompanied by his devoted and heroic Brazilian wife, set sail in a small fishing-craft towards Venice; but being pursued by Austrian vessels, they were compelled to land at random, and not far from the shore his wife, exhausted by the dangers and terrible exertions of their flight, expired in the arms of her husband. G. at length reached Genoa in safety, and from thence embarked for Tunis. He afterwards revisited South America, and acquired the command of an American trading-vessel. In that capacity, he touched at several English ports, where he was received with every testimony of public admiration and sympathy. During the interval which elapsed between the war of 1848 and that of 1859, G. publicly accepted the substitution of monarchy, such as it existed in Piedmont, for the republican form of government, for which he had originally combated, and was therefore free to serve as an irregular auxiliary of the Piedmontese forces on the commencement of hostilities. His services in that capacity were both brilliant and effective, notwithstanding the limited scope assigned for his operations. In the course of the following year (1860), the most triumphant and momentous enterprise of his marvellous career was accomplished. The chief result of the peace of Villafranca, by which the Italian war of 1859 was brought to an abrupt and unsatisfactory termination, was the immediate resumption by the Italian people of the revolutionary and progressive responsibilities, which during the campaign had been vested by the nation in the government of Sardinia. Thus, early in 1860, insurrectionary disturbances broke out in Palermo, and although speedily quelled in the city by the great numerical strength of the Neapolitan garrison, they were constantly repeated throughout the interior of the island, where the insurgents were full of elation and daring, in consequence of G. having transmitted to them the assurance that he would speedily appear himself to head their struggle. In fulfilment of this promise, G. assembled at Genoa a volunteer force of 1070 patriots, and on the 5th of May set sail for the island of Sicily. On the 11th, his two small transport steamers having reached Marsala in safety, the landing of his followers was successfully effected in sight, and partially under fire, of the Neapolitan fleet. On the 15th, in the battle of Calatafimi, 3600 Neapolitan troops were routed by G.'s small force, and to this opening victory may be largely attributed the subsequent success of the entire expedition. It at once cleared the way to Palermo, and inspired G.'s soldiers with irresistible confidence. On the 18th of the same month, G. and his little army of heroes occupied the heights which command Palermo, and after a desperate conflict with the royalist troops, fought his way into that unhappy city, which for several subsequent days had to sustain a ruthless bombardment from the united fire of the Neapolitan garrison and fleet.

The intervention of the British fleet, seconded by the isolated and destitute condition of the garrison shut up in the forts, induced the Neapolitan general to capitulate; and on his departure with his troops, G. remained in undisputed possession of the city

and strongholds of Palermo. His first public enactment was the universal armament of the citizens. On the 20th of July, at the head of 2500 men, he gave battle at Melazzo to 7000 Neapolitans, who were completely defeated, and compelled to evacuate the fortress. On the 25th, the Neapolitans were driven back into Messina, where G. made his triumphal entry on the 27th, the mutinous garrison, terrified at his approach, having compelled their general to submit. Towards the middle of August, G. made a descent in Calabria, and was immediately joined by large bodies of volunteers from all directions, by whom he was accompanied on his memorable and eventful march to Naples. On the 5th of September, G.'s army, which then amounted to 25,000 or 30,000 men, occupied Salerno on the withdrawal of the royalists, and on the 7th, amidst the frenzied enthusiasm of the inhabitants, G. entered Naples, with only one or two friends, to prove to Europe that his advent was that of a welcome liberator, and not of a terror-inspiring conqueror. On the previous day, the capital had sullenly witnessed the withdrawal of King Francis II. to the fortress of Gaeta. Before the close of the month, G. had enacted several judicious public reforms, calculated to increase the popularity of the Sardinian government, of which he was the declared representative, although for a brief space he accepted the title and powers of Dictator. On the 1st of October, his military duties became again paramount, as the royalist troops, numbering 15,000 men, came forth from Capua, and attacked fiercely the whole line of the Garibaldians, spread along the Volturno. For some hours a terrible suspense reigned, and more than once it seemed as if success were about to desert the patriots at the last moment; but finally the royalists were driven back to Capua in disorder, and G. announced the result in his famous telegram—'Complete victory along the entire line.' This was G.'s last triumph; Victor Emmanuel, having re-assumed the command of his army, crossed the papal frontier, routed the troops under Lamoricière, and passed on into the kingdom of Naples, where he was met by G., who immediately relinquished into his sovereign's hands the unconditional disposal of the southern volunteer army, and the absolute sway over the Neapolitan provinces. G. absolutely declined all personal distinction or aggrandisement; and having bid farewell to his heroic comrades, he set sail, on the 9th of November, for his home on the rock of Caprera, there to remain in grand simplicity and retirement till his country may again require his aid and invoke his presence.

The almost fabulous success which has tracked this great soldier's enterprises throughout his entire career is the best evidence of his military genius and heroic qualities. In himself, he presents a unique combination of the social and endearing virtues which attract and rivet enthusiastic friendship, and of those stern and commanding attributes which carry terror into the hearts of opponents, and impose subordination and a sense of duty on the most irregular masses of troops. Of a patriarchal simplicity in tastes and habits, he resembles more the chief of a warlike tribe than the general of an army; his smile of approbation ever gladdens the performance of duty by his men, but his reproof of the laggard or craven-hearted is soothingly fierce. G. has come to be regarded as one of the most incorruptible of patriots and most glorious of heroes, either in ancient or modern times; and the land which has produced and nurtured such a spirit and character may be held to have proved that it has a political and moral vitality, at least as powerful as any other portion of Christendom.

GA'RIEP, otherwise ORANGE, is a river of South Africa, which, after a westward course of 1000 miles enters the Atlantic in lat. 28° 30' S., and long. 16° 30' E. It rises in the *Mont aux Sources*, near lat. 29° S. and long. 30° E., at an elevation of about 10,000 feet above the sea. Throughout nearly its whole length, it forms the northern boundary of the Cape Colony, separating it below the confluence of the Vaal from still independent tribes, and above that point from the Orange Free State or Orange Sovereignty. For the purposes of navigation, this river is almost useless.

GABIGLIA'NO (the *Liris* of the ancients, which separated Latium from Campania) is the largest and most important river of the Neapolitan provinces. It rises in the Abruzzi, in the valley of Nera, and discharges itself into the Mediterranean, in the Gulf of Gaeta, after traversing the province of Terra di Lavoro. The sluggish course of its muddy waters (which, however, are stocked with fish, especially eels) has been mentioned by more than one of the ancient poets:

Non rura quæ Liris quietâ

Mordet aquâ, taciturnus amnis.—Hor. Od. i. 81.

It is asserted that the name G. is derived from an Arabic word, *parîl*, which signifies marsh, plain; it was generally adopted in the 11th c., after the defeat of the Saracens, who had held possession for some time of the neighbouring plains, and had erected a castle at the mouth of the river, which they entitled Garilianum. This derivation is appropriate to the marshy swamps surrounding the river, amidst which Marius found concealment when pursued by Sulla. The banks of the G. are memorable for the famous battle fought there between the French, in 1503, and the Spaniards, commanded by Gonzalvo de Cordova, surnamed the Great Captain, in which the former were totally routed.

GARLAND. See CROWN.

GARLIC (*Allium sativum*, see ALLIUM), a bulbous-rooted plant, a native of the East, cultivated from the earliest ages. The stem rises to the height of about two feet, unbranched, and bearing at top an umbel of a few whitish flowers, mixed with many small bulbs. The upper part of the stem before flowering is rolled together into a ring. The leaves are grass-like, obscurely keeled, and not fistulous like those of the onion. Three alternate stamens are 3-pointed, the middle point bearing the anther. The bulb consists of about 12—15 ovate-oblong cloves or subordinate bulbs, which are axillary buds of its scales thus developed; it contains a viscid juice, which is sometimes used as a cement for porcelain, and has a penetrating and powerful alliaceous odour, which indeed pervades the whole plant, with a pungent aromatic taste. It is in general use as a condiment with other articles of food, and to many it is in this way very agreeable.

Common Garlic (*Allium sativum*).

to others, it is disgusting. It is much more largely used in many other countries than in Britain: in Spain, it enters into the composition of almost every dish. Garlic, or its fresh juice, is also used in medicine. It is stimulant, tonic, and promotes digestion; it has also diuretic and sudorific properties, and is a good expectorant, promoting all the excretions. Applied externally, it is a rubefacient, and is used to stimulate indolent tumours. A liniment of oil and garlic juice is sometimes applied to the chest in infantile convulsions. In some cases of deafness, much benefit is obtained from a clove of garlic or a few drops of the juice put into the ear. Garlic is also used as an anthelmintic. It owes its properties chiefly to oil of garlic (see following art.). Garlic abounds also in mucilage. The cultivation of garlic is extremely easy; it is generally propagated by its cloves.—Many of the species of *Allium* are popularly called garlic, with some distinctive addition. *A. oleraceum* is sometimes called Wild Garlic in England, and its young and tender leaves are used as a pot-herb. Its leaves are semi-cylindrical, and grooved on the upper side. The stamens are all simple.

GARLIC, Oil of. When cloves of garlic are distilled with water, about 0·2 per cent. of a brown heavy oil, with an acrid taste, and a strong disagreeable smell, passes over. By careful rectification from a salt-water bath, about two-thirds of the oil may be obtained in the form of a yellow liquid, which is lighter than water, and which, when treated with chloride of calcium (in order to dry it), and subsequently distilled from fragments of potassium, comes over pure and colourless as sulphide of allyl, an organic compound of very considerable interest, whose formula is C_3H_3S . The crude oil also contains oxide of allyl (C_3H_3O), and a compound of allyl still richer in sulphur than the sulphide.

Sulphide of allyl exists not only in oil of garlic, but also in the oils of onions, leeks, cress, alliaria, radishes, asafetida, &c. It is a light, clear, pale-yellow oil, with a penetrating odour of garlic; it boils at 284° , and dissolves readily in alcohol and ether.

Sulphide of allyl may be obtained from essential oil of black mustard (which in its purified form is represented by $C_3H_3CNS_2$, and may consequently be regarded as sulphocyanide of allyl) by distillation with sulphide of potassium. The reaction is exhibited in the following equation:

We may perform the converse experiment, and obtain oil of mustard from oil of garlic by mixing alcoholic solutions of sulphide of allyl and corrosive sublimate, when a white precipitate is formed, represented by $C_3H_3S, 2HgS + C_3H_3Cl, 2HgCl$, and distilling this compound with sulphocyanide of potassium, in which case oil of mustard will be found among the products.

The pungency of horse-radish, scurvy-grass, and other allied plants, is due to the presence of this essential oil of mustard or sulphocyanide of allyl.

We shall postpone the further consideration of sulphocyanide of allyl to the article **MUSTARD, Oil of**, but shall take this opportunity of very briefly noticing the chief members of the allyl series, which has recently been studied with very fruitful results by several of our most eminent chemists.

Free allyl (C_3H_3 , or, more probably, $C_3H_3C_2H_5$) is a very volatile combustible fluid, with a combined odour of ether and radishes. It is obtained by the action of sodium on iodide of allyl.

Allylic alcohol (C_3H_3O, HO) is metameric with

acetone and propyllic aldehyde, but it differs from them in its properties. It is obtained by the action of ammonia on oxalate of allyl.

Allylic ether or oxide of allyl (C_3H_3O) has been formed in at least two different ways, but the reactions accompanying its formation are too complicated for notice in this article. It exists ready formed in small quantity in oil of garlic, and some other oils that resemble it, and may be obtained by the decomposition of oil of black mustard.

The chloride, bromide, and iodide of allyl have all been obtained. The iodide is a colourless liquid, of specific gravity 1·789, with an ethereal, and somewhat alliaceous odour. It is decomposed by digestion with a watery solution of ammonia, and on distillation with potash, a volatile base with a fishy ammoniacal odour is formed. It is probably allylia, or allyl-amine (C_3H_3N or $C_3H_3H_2N$), the basic volatile alkali of the allylic series, which has also been obtained by a different process, and corresponds to ethylia or ethyl-amine in the ethylic series.—Miller's *Elements of Chemistry*, 2d edit., 1862, vol. 3, pp. 574—584; Goup-Besanez, *Lehrbuch d. Chemie*, vol. 2, pp. 266—272; and the recent memoirs of Berthelot and Luca, Hofmann and Cahours, &c.

GARNET, a precious stone, some of the varieties of which are of great beauty; while some are less highly prized than other not more beautiful minerals, because much more common. Garnets are found most generally in mica-slate, hornblende slate, and gneiss; less frequently in granite and granular limestone; sometimes in serpentine and lava. There are numerous varieties, differing considerably in chemical composition; anhydrous silicates of alumina and lime or magnesia, coloured with oxide of iron, of manganese, or of chrome. The colour is various, generally some shade of red, brown, black, green,

Garnet:

1, a detached crystal; 2, portion of rock with imbedded crystals.

or yellow. Colourless and white specimens also occur. Red garnets sometimes contain so much iron as to be attracted by the magnet. The coarser variety of G., known as Common G., is generally found massive, often forming a very considerable part of the rock in which it occurs, so as even to be used as a flux in the smelting of iron. Crystallised garnets are also often very numerous in the rock which contains them; the crystals are sometimes very small, almost imperceptible grains; sometimes they are as large as a man's fist. The primary form of the crystal is a cube, but the common secondary forms are a rhombic dodecahedron, and an acute double eight-sided pyramid, the summits of which are abruptly acuminate by four planes.—Noble G., or Precious G., also called *Almandine*, is generally of a crimson-red colour, sometimes of so deep a tint, that jewellers hollow it out beneath, or place at the back of it a plate of silver. It is sometimes transparent, sometimes only translucent. It is found in some of the mountainous parts both of England and Scotland, but the finest garnets are imported from Syriam, in Pegu. A Syriam G.,

of a velvety black colour, without defect, is valued at about half the price of a blue sapphire of the same weight. The large specimens of the precious G. are generally engraved with figures, and thus acquire a very high value.—A variety of G., known as *Grossularia*, from its resemblance in form, size, and colour, to a green gooseberry, is brought from Siberia.—Cinnamon Stone (q. v.) is a variety of garnet.—Pyrope, Vesuvian, and Epidote are nearly allied to it.—Powdered garnets are often used for polishing and cutting other stones; this powder is known to lapidaries as *Red Emery*.

GARNISH, GARNISHMENT, GARNISHEE (Fr. *garnir*, to furnish). In English law, to garnish is to warn, and garnishment signifies a warning given to one for his appearance in court. But garnishment in its more usual sense is applied to the notice which a person sued in an action of detainee, and pleading the interest of a third party, is entitled to require to be served on that party. By the custom of London and certain other towns, a practice has existed from time immemorial, whereby a plaintiff suing in the local court was entitled to attach the property of the defendant in the hands of a third person, who was called the garnishee. See FOREIGN ATTACHMENT. But until the passing of the Common Law Procedure Act, 1854, there existed no means in England whereby a creditor could attach the property of his debtor in the hands of third persons in direct satisfaction of his claim. By sections 60—65 of this statute, it is now provided, that any one having obtained a judgment in one of the superior courts at Westminster, may require his debtor to be examined as to the debts due to him, and on the statement of the judgment debtor, all debts owing to him by third parties, called garnishees, may be attached in satisfaction of the plaintiff's claim. If the garnishee pay, he is forthwith discharged of the debt to his creditors, but if he fail to pay, and does not dispute the debt, the judge may order execution against him. It is to be observed that, under this statute, garnishment can still be obtained only where judgment has been obtained. Debts due to a defendant during the currency of an action, therefore, cannot be attached. In this respect, the remedy is less effectual than the custom of foreign attachment. In Scotland, debts due to a defender may be attached, both after judgment and on the dependence of an action. See ARRESTMENT.

GARNISHED, in Heraldry. Any charge is said to be garnished with the ornament set on it.

GARONNE (anc. *Garumna*), the principal river in the south-west of France, rises within the Spanish frontier in the Val d'Aran, at the base of Mount Maladetta, in the Pyrenees. About 26 miles from its source, it enters the French territory in the department of the Haute Garonne, flows in a general north-east course to Toulouse, then bends to the north-west, and continues to flow in that direction until, joined by the Dordogne, about 20 miles below Bordeaux, and widening afterwards into the estuary which bears the name of the Gironde, it enters the Atlantic at the Pointe de Grave. The basin of the G. is upwards of 200 miles in length, and about an equal extent in width at its broadest part; although narrowing in the north-west to a width of only 25 miles. The total length of the river is about 350 miles; and its natural navigation, which, however, is much impeded above Toulouse, commences at Cazères, 282 miles from its embouchure. At Bordeaux, the river attains a breadth of 1603 feet. Its principal affluents are the Tarn, Aveyron, Lot, and Dordogne, on the right; and on the left, the Save, Gers, and Baise. At

Toulouse it is joined by the Canal du Midi, which, running eastward to the Mediterranean, forms with the G. a means of communication between that sea and the Atlantic. The valley of the G. is noted for the beauty of its scenery, and its abundant produce of corn and wine.

The estuary of the Gironde is 40 miles in length, and about 4 miles in average breadth. Below Blaye, its shores consist of bare rocks and bleak and dreary heath.

GARONNE, HAUTE, a department in the south of France, is bounded on the S. by the Pyrenees, and on the W. by the departments of Hautes Pyrenees and Gers. It has an area of 2369 square miles, and a population of 481,247. It is watered throughout by the Garonne, from which it derives its name, and within the basin of which it wholly lies. Occupied in the south by a branch of the Pyrenean range, the slope of the department, and the course of its streams, are toward the north and north-east, where the land is generally level. The soil is on the whole good; that in the valleys is remarkably productive, and brings forth heavy crops of grain, maize, flax, and potatoes. Orchard-fruits, with melons and tobacco, are produced in abundance, and the annual yield of wine is about 14,300,000 gallons, two-thirds of which is exported. Minerals also abound, but, with the exception of iron, have not yet been obtained in any great quantity. The chief manufactures are woollen and cotton fabrics and hardware; and these, with timber, cattle, wine, and preserved meats, are the principal exports. The department of Haute G. was formerly divided between the provinces of Languedoc and Gascony. It is divided into the four arrondissements of Toulouse, Muret, St Gaudens, and Villefranche, with Toulouse as capital.

GARRICK, DAVID, actor and author, was born at Hereford in 1716, and educated at the grammar school of Lichfield. After a short residence at Lisbon with an uncle, who was a wine-merchant in that city, he returned to England, and in 1735 became a pupil of the famous Dr Johnson; but in the course of six months, master and pupil both proceeded to London, with the view of improving their fortunes. G. attempted the study of law, but an irresistible instinct soon urged him to the stage. He made his *début* at Ipswich in 1741, as Aboan, in the play of *Oroonoko*, and obtained a great success. Encouraged by this, he ventured to appear before a London audience in the autumn of the same year, and in the character of Richard III. was received with prodigious applause. The fashionable theatres were emptied to gaze upon the new star that was shedding an unwonted lustre on the obscurity of the Goodman's Fields' stage, and the other theatrical celebrities, such as Quin and Cibber, could not conceal their chagrin and disgust. In the following year, G. accepted an engagement at Dublin, where he excited the Hibernian enthusiasm to a miraculous degree. The playhouse, we are told, was so crowded, 'that a very mortal fever was produced, which was called Garrick's fever.' In 1747, he became joint-patentee of Drury Lane, and two years after, married Mademoiselle Violette, a foreign danseuse; a circumstance which, somehow or other, he feared might expose him to ridicule, and to prevent such a thing, he got his friend Mr Edward Moore 'to write a diverting poem upon his marriage.' This was not the only occasion when his sensitiveness to malicious banter induced him to forestall the wits and critics, and so blunt the edge of their jests and criticisms. Before acting *Macbeth* for the first time, he wrote a humorous pamphlet, reflecting on the 'mimical behaviour of a certain fashionable

faulty actor,' to wit, Garrick himself. In 1763 he paid a visit to Italy, and in 1769 projected and conducted the memorable jubilee at Stratford-upon-Avon in honour of Shakspeare. He died in London, January 20, 1779, having accumulated a fortune of £140,000. G. ranks as one of the very greatest—perhaps the very greatest—of English actors. He exhibited a Shaksperian universality in the representation of character, and was equally at home in the highest flights of tragedy and the lowest depths of farce. But the *naturalness* which so wonderfully marked him on the stage, often forsook him in real life. He was jealous to an extreme, and had an unbounded stomach for flattery. His friend Goldsmith hits off his character happily in the poem, entitled *Retaliation*. As a dramatic author, G. does not hold a high place. He wrote about 40 pieces, some original, but mostly adaptations of old plays. His numerous prologues and epilogues, however, deserve considerable praise.

GARRISON (Fr. *garrison*, from low Latin *garnisio*, military furniture), the troops occupying a town or fortress, either for defensive purposes, or merely as ordinary quarters.

GARRISON, WILLIAM LLOYD, a distinguished American abolitionist, the acknowledged leader of the advocates of immediate emancipation in the United States, was born at Newburyport, Massachusetts, in 1805. Before he was 20 years old, he had acquired no inconsiderable reputation by the articles which he contributed to the *Salem Gazette* and other newspapers. He became, in 1826, the conductor of a paper of his own, the *Free Press*, published at Newburyport; it was, however, unsuccessful, and was soon discontinued. In 1829, he became joint-editor of the *Genius of Universal Emancipation*, an anti-slavery journal published in Baltimore. This paper had previously advocated the gradual abolition of slavery; but Mr G., in the very first number that was issued after his connection with it, distinctly avowed the doctrine that immediate emancipation is the right of the slave, and the duty of the master. Having, soon after, severely denounced certain persons engaged in the domestic slave-trade, which he stigmatised as 'domestic piracy,' he was tried and convicted for a libel. Unable to pay the penalty imposed by the court, he was sent to prison, where he remained several weeks. At length, a generous friend paid the fine, and released him. On the 1st of January 1831, G. issued in Boston the first number of the *Liberator*, a weekly anti-slavery paper, with which his fame has since become indissolubly associated. The unsparring, not to say virulent denunciation with which G. assailed the institution of slavery and all those voluntarily, however remotely, connected with it, was not long in arousing attention in every part of the country; while it excited in the Southern States the utmost exasperation. Almost every day brought him letters from the South, containing threats of violence, and even assassination. At length, the legislature of Georgia went so far as to offer a reward of 5000 dollars to any one who should arrest and prosecute him to conviction under the laws of that state. Meanwhile, he was repeatedly mobbed at home, and his life was more than once in the utmost peril even in Boston. But nothing could turn him from his course. Although there has been some abatement in the tone of the *Liberator*, G. has not in a single material point modified his views in regard to slavery in the 31 years during which that paper has been published. The early severity of his denunciations, as his friends allege, with some show

of reason, was necessary, in order to arouse the conscience of the nation from its apathy respecting the wrongs of the African race. It would perhaps be less easy to excuse the unsparring invective with which Mr G. has so often assailed those friends of emancipation who have thought it right to pursue a course different from his own.

It is proper to remark, that Mr G. and his devoted followers have always disclaimed any purpose of exciting the slaves to assert their own freedom by force. They profess to rely solely on arguments and 'moral suasion' addressed to the consciences of the dominant race. They are also non-resistants; and not only refuse to hold any office in the federal republic, but are conscientious even against voting for such an office, for they consider this would be an indirect acknowledgment of the rightfulness of a government supported by military power, and contaminated by a compromise with slavery.

GA'RRROT (*Clangula*), a genus of the oceanic section of Ducks (q. v.), having the bill shorter than the head. One species, the **GOLDEN-EYE** (*C. vulgaris* or *C. chrysophthalmus*), a bird not quite so large as a

Golden-eye (*Clangula vulgaris*).—Male.

widgeon, is a common winter visitant in Britain, appearing in small flocks, most frequently in severe weather, not only in estuaries, but on the lakes and rivers of inland parts of the country, as it does on those of all the central and southern parts of Europe, and equally on those of the temperate parts of Asia and North America. It breeds in arctic and sub-arctic regions, preferring wooded districts, and forms its nest either on the ground, in the crevice of a rock, or the hole of a tree. The parent birds are said to transport their young from the nest to the water, holding them under the bill, and supported by the neck. The Lapps take advantage of the predilection of the golden-eyes for making their nests in holes, by setting up boxes for them, and then robbing them of their eggs.—Another British species is the **HARLEQUIN G.**, or **HARLEQUIN DUCK** (*C. histrionica*), but it is only a rare winter visitant. Like the golden-eye, it is a native of the northern parts of the world generally. The male is curiously streaked and marked with white.—The **BUFFET-HEADED G.**, or **BUFFET-HEADED DUCK** (*C. albeola*) is of extremely rare occurrence in Britain, but is very common in North America, where it is often called the Spirit Duck, a name which is said to have been bestowed in allusion to its power of eluding observation by diving. It is rather smaller than the golden-eye and harlequin garrot. The flesh of the garrote is eaten, but not very highly esteemed.

GARROTTE (Spanish *garrote*, a stick or cudgel), a mode of execution practised in Spain and the

Spanish colonies. Originally, it consisted in simply placing a cord round the neck of a criminal, who was seated on a chair fixed to a post, and then twisting the cord by means of a *stick* (whence the name) inserted between it and the back of the neck, till strangulation was produced. Afterwards, a brass collar was used, containing a screw, which the executioner turned till its point entered the spinal marrow where it unites with the brain, causing instantaneous death. The inquisitors were wont to grant as a favour this mode of strangulation, before being burned, to such condemned persons as recanted. If the executioner was unskilful, however, the pain was sometimes very great. Llorente (*Hist. de l'Inq.*, t. iii. p. 472) mentions that at an *Auto da Fé* (q. v.) at Cuenca, a poor Jew, who had obtained this dismal privilege of preliminary strangulation, noticing the bungling manner in which the executioner had performed the operation on the two who preceded him, said to the latter: 'Peter, if you are likely to strangle me so clumsily, I would much rather be burned alive.' The same process was also applied as a species of torture to the limbs, or to such portions of the body as might be injured with comparative impunity. It is probable that the Spaniards adopted the garrotte from the Moors; at all events, in its primitive form, it exactly resembles the punishment of the bowstring in use among Mohammedan nations.—Garrotting is also the name given in England and Scotland to a species of robbery which has recently become rather common, in which the robbers suddenly come behind their victim, and throwing a cord, or handkerchief, or something of the sort, round his neck, produce temporary strangulation till their purpose is effected.

GARROVILLAS-DE-ALCONETAR, a small town of Spain in the province of Cáceres is situated 20 miles north-west of the town of that name, on the left bank of the Tagus. It has manufactures of linen and woollen fabrics, and some trade in grain, cattle, and fruit. Pop. 6573.

GARTER. See **BEND**.

GARTER, ORDER OF THE. The order of the garter was instituted by King Edward III., and though not the most ancient, is one of the most famous of the military orders of Europe. Selden says that it 'exceeds in majesty, honour, and fame all chivalrous orders in the world.' It is said to have been devised for the purpose of attracting to the king's party such soldiers of fortune as might

be likely to aid in asserting the claim which he was then making to the crown of France, and intended as an imitation of King Arthur's round table. The round table was erected at Windsor, and the knights and nobles who were invited from all parts of the world were exercised at tilts and tournaments as a preparation for the magnificent feasts that were spread before them.

Star of the Order of the Garter.

That general 'jousts and tournaments' of this description were held at Windsor, is known from the letters summoning them bearing date 1st January 1344, and quoted by Sir Harris Nicolas in his *Orders of Knighthood*, i. p. 6; and from the narrative of Froissart, who connects them with the institution of the order. The original number of the knights of the garter was twenty-five, his majesty himself making the twenty-sixth. The story that

the Countess of Salisbury let fall her garter when dancing with the king, and that the king picked it up and tied it round his own leg; but that, observing the jealous glances of the queen, he restored it to its fair owner with the exclamation: *Honi soit qui mal y pense*, is about as well authenticated as most tales of the kind, and has, moreover, in its favour that it accounts for the otherwise unaccountable emblem and motto of the order. Sir Harris Nicolas, whose error does not usually lie in the direction of credulity, says, that though the writers on the order have treated it with contempt, they have neither succeeded in shewing its absurdity, nor suggested a more probable theory. Various dates are assigned to the order of the garter. Froissart, as above mentioned, gives 1344, and fixes on St George's day (23d April), 1344; but Stow, and, it is said, the statutes of the order, fix it six years later—viz., 1350. The original statutes have long since perished, and little reliance can be placed on the modern copies of them, and nothing is known on the subject with precision till the compilation of the *Black Book* in the latter part of the reign of Henry VIII. In these circumstances, Sir Harris Nicolas is of opinion, that, though founded at the former period, it was not till the latter that the order was finally organised, and the companions chosen. It was founded in honour of the Holy Trinity, the Virgin Mary, St Edward the Confessor, and St George; but the last, who had become the tutelary saint of England, was considered its special patron; and for this reason it has always borne the title of 'The Order of St George,' as well as of 'The Garter.' A list of the original knights, or knights-founders, is given by Sir Harris Nicolas.

Collar, Badge, and Garter.

The well-known emblem of the order is a dark-blue ribbon edged with gold, bearing the motto *Honi soit qui mal y pense*, in golden letters, with a buckle and pendant of gold richly chased. It is worn on the left leg below the knee. The mantle is of blue velvet, lined with white taffeta, and on the left breast a star is embroidered. The hood and surcoat are of crimson velvet, lined with white taffeta. The hat is of black velvet, with a plume of white ostrich feathers, in the centre of which there is a tuft of black herons' feathers, all fastened to the hat by a band of diamonds. The collar is of gold, and consists of 26 pieces, each in the form of a garter. The 'George' is the figure of St George on horseback encountering the Dragon; is worn to the collar, and there is a 'lesser George' pendant to a broad dark-blue ribbon over the left shoulder. The Star, which is of eight points, is silver, and has upon the centre the Cross of St George, gules, encircled with the garter. The officers of the order are—the Prelate (the Bishop of Winchester), the Chancellor (the Bishop of Oxford), the Registrar (the Dean of Windsor), the Garter King of Arms (q. v.), and the Usher of the Black Rod.

GARTER KING OF ARMS is also the Principal King of Arms in England. Though held by the same person, they are distinct offices. The first was instituted for the service of the order of the Garter (see **GARTER**), not on its first foundation, but afterwards by Henry V. as sovereign, with the

advice and consent of the knights-companions. The peculiar duty of Garter King of Arms is to attend upon the knights at their solemnities, to intimate their election to those who are chosen by the order, to call them to be installed at Windsor, to cause their arms to be hung up over their stalls, and to marshal their funeral processions, and those of royal personages, and of members of the higher nobility. In the capacity of principal King of Arms, he grants and confirms arms, under the authority of the Earl Marshal, to whom he is not subject as Garter King of Arms. All new grants or patents of arms in England are first signed and sealed by Garter King of Arms, and then by the king of the province to which the applicant belongs. See HERALD'S COLLEGE.

GARTH, SAMUEL, an eminent physician, and a poet of considerable reputation, was born at Bolam, in the county of Durham, in 1660. He was a member of Peterhouse, Cambridge, and graduated as M.D. in 1691. In the following year, he settled in London, and was admitted into the College of Physicians, in which institution he subsequently held several important offices. His professional skill was associated with great conversational powers, and he soon acquired a very extensive practice. The year 1700 presents an incident in G.'s life which did him everlasting honour. He it was who stepped forward to provide a suitable interment in Westminster Abbey for the neglected corpse of Dryden, which he caused to be brought to the College in Warwick Lane; and he pronounced a eulogium over the great poet's remains. On the accession of George I., he received the honour of knighthood, was appointed physician in ordinary to the king, and physician-general to the army. He died in London, January 18, 1718.

G. is best known in our literary history as the author of *The Dispensary*, a poetical satire on the apothecaries and those physicians who sided with them in opposing the project of giving medicine gratuitously to the sick poor. The sketches of some of his contemporaries—as, for instance, Drs Gould, Tyson, and How, who are introduced into the poem as 'obsequious Umbra,' 'slow Carus,' and 'shrill Querpo'—are severe; and although, doubtless, exaggerated by poetic licence, must have been true to nature, or the work could not have obtained such an immediate and extensive circulation. The first edition came out in 1699, and the second and third followed in the course of a very few months. In 1706, he brought out the sixth edition with considerable additions. In 1715, he published a poem entitled *Claremont*, and in 1717 he superintended and contributed to a translation of Ovid's *Metamorphoses* by some of the most eminent writers of that age—Addison, Pope, Gay, Congreve, and Rowe being amongst the contributors.

Pope frequently refers to him, both in his letters and in his poems, with great respect—

And we, too, boast our Garth and Addison.

The second *Pastoral* was dedicated to G.; and in a letter to Jervis in 1718, Pope states that he entertains 'the truest concern for his loss.'

GÄRTNER, FRIEDRICH VON, a distinguished German architect, was born at Coblenz in 1792. His father, also an architect, removed in 1804 to Munich, where young G. received his first education in architecture. To complete that education, he travelled in 1812 to Paris, and in 1814 to Italy, where he spent four years in the earnest study of antiquities. The fruits of this labour appeared in 1819 in some views, accompanied by descriptions, of the principal monuments which have been preserved in Sicily (*Ansichten der am Meisten erhaltenen Monu-*

mente Siciliens, Lithographien mit erläuterndem Text). After a visit to England, he was called, in 1820, to the chair of Architecture in the academy of Munich. With this appointment began his work as a practical architect. Many of the architectural ornaments of Munich, and various other buildings throughout Germany, as well as the new royal palace at Athens, are built after his plans. In the style of his works, which have all a common impress, G. represents the renaissance of the mediæval architecture in its Romanesque forms. The round arch with its accompaniments prevails in them all. G. was rewarded with the fellowship of several academies, with orders of his own and foreign countries, with a degree from Erlangen, with the office of head government-surveyor of buildings, and with the directorship of the Academy of Arts in Munich. He died in the midst of his labours, 21st April 1847.

GARTSHEERIE, a village of Lanarkshire, in the parish of Old Monkland, is noted for its extensive ironworks. In the immediate neighbourhood are the ironworks of Dundyvan, Clyde, and Calder, all of which, together with Coatbridge, contribute to the iron-trade of Glasgow. See article LANARKSHIRE.

GAS, ANALYSIS OF. This department of analysis originated in the attempts of various chemists, during the last quarter of the 18th, and the first quarter of the present century, to determine the volume of oxygen in specimens of atmospheric air taken from different localities. The general principle on which the early Eudiometers (q.v.) were constructed, was that of exposing atmospheric air to the action of some substance which combined with its oxygen. Various eudiometers and endometrical processes were devised by Priestley, De Marté, Guyton, Seguin, Volta, Berthollet, Hope, Henry, Pepys, Ure, &c., which are now only of interest in an historical point of view. They were not only almost exclusively limited to the determination of the quantity of oxygen, but they were more or less imperfect in their action; and the analysis of the gases generally did not become developed into a system until Professor Bunsen of Heidelberg, some 20 years ago, began to devote himself to the subject. Ingenious instruments for the analysis of gaseous mixtures have recently been devised, not only by Bunsen, but by Regnault and Reiset, Williamson and Russell, and Frankland and Ward. The instrument devised by the last-named gentlemen we shall presently describe; but before doing so, we must say a few words on the collection of gases for analysis. In collecting gases, we usually employ small glass vessels, the contents of which, consisting of water, mercury, or air, are displaced by the gas to be analysed. Of these three fluids, water is the least capable of general application, inasmuch as it gives rise to phenomena of absorption and diffusion, which modify the composition of the gas that is to be collected, and gases are more or less soluble in it. For the best methods of collecting gases from mineral springs and waters, from volcanic lakes, geysers or boiling springs, from openings in rocks, clefts of glaciers, furnaces, fissures in volcanic craters, &c., we must refer to Bunsen's *Gasometry*, translated by Roscoe, 1857. Again, it must be recollected that the nature of the gas that is evolved often varies with the progressive phases of a decomposition, as, for example, in the process of coking, or in the phenomena of combustion and decomposition occurring in the strata of a furnace. In these cases, it is necessary to collect a series of specimens during the progress of the decomposition.

Our limited space will not allow of our entering into the various details of the complicated apparatus employed by Frankland and Ward, which is regarded as the best that has yet been invented. A full account of it may be found in their Memoir in the *Quarterly Journal of the Chemical Society*, or in Williams's *Handbook of Chemical Manipulation*. The following remarks, which we take with slight modifications from their Memoir, will, we trust, sufficiently explain the manner of using this apparatus. We take as an example an analysis of atmospheric air. A few (three or four) cubic inches of air, freed from carbonic acid, having been introduced into the tube I, it is transferred into F for measurement by opening the cocks *l*, *f*, and placing the tube

A, a tripod, with levelling screws; BB, a vertical pillar, to which is attached, C, a mercurial trough, movable by a rack and pinion, *ac*; DD, a glass cylinder, 30 inches long, with an internal diameter of 4 inches, containing three tubes, F, G, H, which communicate with one another and with the exit-pipe, *k*, by the apparatus E *f* E. The rest of the figure will be sufficiently intelligible from the description given in the text.

F in connection with the exit-pipe *k*; the transference can be assisted, if necessary, by elevating the mercurial trough C. (The part marked *b* in the figure is merely the tubular well of the mercurial trough C.) When the air, followed by a few drops of mercury, has passed completely into F, the cock *l* is shut, and *f* turned, so as to connect F and H with *k*. Mercury is allowed to flow out until a vacuum of two or three inches in length is formed in H, and the metal in F is just below one of the graduated divisions; the cock *f* is then reversed, and mercury very gradually admitted from G, until the highest point in F exactly corresponds with one of the divisions upon that tube: we will assume it to be the sixth division, there being ten divisions in all. This adjustment of mercury, and the subsequent readings, can be very accurately made by means of a small horizontal telescope, placed at a distance of about six feet, and sliding on a vertical rod. The height of the mercury in H must now be accurately determined; and if from the number thus read off, the height of the sixth division above the zero of the scale in H is deducted (the scale on H is not marked in the figure), the remainder will express the true volume of the gas, no corrections being required for variations of temperature, atmospheric pressure, tension of aqueous vapour, &c.

Hydrogen, in the proportion of half the volume of the air used, must now be passed into I, and from thence into F, when the volume of the mixed gases must be again determined, as before. An electric spark must now be passed through the mixed gases in F by means of the platinum wires at *m*. A slight explosion occurs, after which we observe a considerable contraction in the volume of the mixed gases. The determination of this contraction terminates the analysis. One third of the contraction thus determined represents the volume of oxygen contained in the air submitted to analysis, and in this case, as oxygen and nitrogen were the only gases present, the estimation of the former also determines the latter. Such an analysis as that which we have described is termed a direct determination; in other cases, we employ an indirect method.

1. The method of direct determination is applicable to mixtures of the following gases: carbonic acid, oxygen, olefiant gas, and carbonic oxide. If all these gases are present in the specimen to be analysed, a few drops of a concentrated solution of potash is introduced into the apparatus, after a measured quantity of the gas has been transferred to it as before; the carbonic acid is speedily absorbed by the potash, and converted into carbonate of potash. The remaining gas is remeasured at the same pressure as before, and the difference of the two measurements represents the volume of the carbonic acid that was present. The remaining gas is next brought into contact with a few drops of a strong solution of pyrogallous acid, which is introduced into the apparatus. In a few minutes, the whole of the oxygen is absorbed by the acid solution, which assumes a deep blood-red colour. The remeasurement of the gas at the original pressure gives the volume of oxygen in the mixture.

The absorption of the olefiant gas is effected by the introduction into the tube I of a coke-bullet saturated with a solution of anhydrous sulphuric acid in oil of vitriol. This absorption occupies far more time than that of the preceding gas, an hour or more being required, and the residual gas contains sulphurous acid and the vapour of anhydrous sulphuric acid, which must be removed by a few drops of a strong solution of potash. The residual gas being again measured in F, the diminished pressure represents the volume of olefiant gas. The carbonic oxide is then determined by a solution of dichloride of copper, which is best prepared by allowing a concentrated solution of the protochloride to be in contact with copper turnings in a stoppered bottle for some days. The gas must be brought in contact for ten minutes with a little of this solution, introduced into the apparatus. The pressure of the gas is again measured, and determines the volume of carbonic oxide that has been absorbed. This gas is, however, usually determined by the indirect method.

2. The method of indirect determination is especially applicable to mixtures of the following gases: hydrogen, light carburetted hydrogen, carbonic oxide, and nitrogen. We explode a known volume of the mixture of these gases in the tube F, with an excess of oxygen, and determine (1) the diminution of volume after the explosion, and (2) the volume of carbonic acid produced by the combustion. The gas that remains after the absorption of the carbonic acid (by a solution of potash), consists merely of nitrogen, with any excess of oxygen beyond what was necessary. The volume of oxygen determined by explosion with hydrogen, subtracted from the residual gas, gives the amount of nitrogen contained in the mixture. For the determination of the respective volumes of nitrogen, hydrogen, carbonic oxide, and light carburetted hydrogen, we have the

following data—viz. (1) the volume of the gas taken for analysis, which we will call A; (2), the volume of the combustible gases contained in it, which we will call A', and which is ascertained by deducting from A the amount of nitrogen determined as above; (3), the contraction of volume on explosion, which we will call C; and (4) the volume of carbonic acid generated on explosion, which we will call D; and we likewise know that on exploding one volume of hydrogen with an excess of oxygen, the contraction of volume is expressed by 1.5; that on similarly exploding one volume of carbonic oxide, the contraction is expressed by 0.5, while one volume of carbonic acid is produced; and that with light carburetted hydrogen the contraction is represented by 2.0, while one volume of carbonic acid is produced. Hence, if we call w, x, y, z , the unknown volumes of nitrogen, hydrogen, carbonic oxide, and light carburetted hydrogen, we see at once that $w = A - A'$, and $x = A' - D$; and the above numerical data give us the equations

$$C = \frac{3x}{2} + \frac{y}{2} + 2z, \text{ and } D = y + z; \text{ whence}$$

$$y = \frac{3A' - 2C + D}{3}, \text{ and } z = \frac{2D - 3A' + 2C}{3},$$

which affords the complete solution of the analytical problem.

If, on the application of these formulae to the results of an analysis, one of the quantities w, x, y, z is found = 0, or a small negative result, it obviously follows, that the gas whose volume is represented by the letter in question, is not present in the mixture.

For further details regarding this somewhat difficult branch of chemical analysis, we must refer to Bunsen's treatise, and to the articles 'Analyse für Gase,' in the second edition of Liebig, Poggendorff, and Wöhler's *Handwörterbuch der Chemie*; and 'Gasometric Analysis,' in the *English Cyclopædia—Arts and Sciences*, vol. iv.

GAS (LIGHTING BY) is the best and most economical mode of obtaining artificial light as yet brought into use; though hardly known at the beginning of the present century, it has since been gradually extending. It may now be said to be universal in the cities and towns of Europe; it is making rapid progress in North America, where it has long been used in the principal cities of the United States and of Canada, and it is spreading rapidly in the smaller towns. Its introduction into South America and into Asia has been more recent, and its progress there, as might have been expected, is much slower. It has also been introduced into the principal towns in Australia and Tasmania.

From 1658 to 1739, the attention of men of science in England had been repeatedly turned to the streams of inflammable air issuing from wells and mines in the coal districts, various communications on the subject having been read before the Royal Society of London. In the last-mentioned year, the Rev. Dr John Clayton, dean of Kildare, gave an account of experiments in which he had distilled gas from coal. It was not, however, till 1792 that the possibility of applying gas, distilled from coal, to the production of artificial light was demonstrated. In that year, Mr William Murdoch constructed apparatus by which he lighted his house and offices at Redruth, in Cornwall. In 1798, he lighted part of the manufactory of Messrs Bolton and Watt at Soho, and in 1805 he lighted the cotton-mills of Messrs Phillips and Lee at Salford. A proposal was made by M. Le Bon to light a portion of Paris with gas in 1802. In the succeeding year, Mr Winsor commenced lecturing on the subject in London. He being a man

of a sanguine and enthusiastic temper, his strong statements probably tended to retard rather than advance the new art. He promised to every depositor of £5 an income exceeding £500 per annum, and he urged the government to take the matter into their own hands, as a certain means not only of clearing off the national debt, but of securing a permanent and large revenue to the country. The chartered Gas Company of London, which was the first company incorporated, obtained their act of parliament in 1810. At that time, Mr Winsor, who had been instrumental in establishing the company, was employed by them, but in 1813 they found it necessary to engage the late Mr Samuel Clegg, who, from the year 1805, had been engaged in promoting the use of gas, and to whose ingenuity and scientific skill the chartered company, as well as the community, were greatly indebted. Mr Clegg was the inventor of the hydraulic main, of the wet-lime purifier, and of the wet gasmeter, all which were essential to the success of gas lighting.

As the first gas applied to artificial lighting was obtained from coal, so, owing to the economy attending its manufacture, the use of any other material only occurs when coal cannot be obtained except at an exorbitant price, and where other gas-yielding materials are unusually cheap. Resin and oils are the best substitutes for coal.

Destructive distillation by the action of heat is in all cases the means employed to disengage the gas from the raw material, the apparatus and processes being modified to suit the material operated upon. As the manufacture of coal-gas is not only the most general, but also the most interesting of these processes, and as the mode of storing, distributing, and using the gas is the same in all, the manufacture of coal-gas only will be here described.

As a branch of manufacturing industry, coal-gas-works occupy an important position, not only from the immense capital permanently embarked, and the great number of hands employed in them, but also from the demand created by them for coal, lime, &c., and for ironwork, brasswork, and gasmeters. In London alone, the aggregate share capital of 17 gas companies amounts to £5,000,000, independently of large sums of borrowed capital. In England, there are above 400 gas companies; in Scotland, above 180; in Ireland, above 60; and there are in the three kingdoms about 130 gas-works, the property of individuals or of corporations. The coals best adapted for the manufacture of gas, are those known in England by the name of cannel, and in Scotland by the name of parrot coals. The English caking coals, of which a great part are obtained in the neighbourhood of Newcastle-on-Tyne, are, however, from their cheapness and the superior quality of the coke which remains after distillation, more extensively used than any other. In Scotland, parrot coals are used almost exclusively. Cannel is used exclusively in Liverpool, Manchester, and some other towns; a proportion of cannel or of Scotch parrot is used with caking coal in London and other places to improve the quality of the gas, but in England generally the gas is made from caking coal. The coke of the English cannel coals is of fair quality, though inferior to that of the caking coals. The coke of the Scotch parrot coals is very inferior, that of some being altogether worthless.

The English caking coals yield from 8000 to 10,000 cubic feet of gas per ton, of illuminating power varying from 10 to 12 sperm candles to a burner consuming five feet per hour. The English cannel coals yield about 10,000 cubic feet per ton, of illuminating power varying from 20 to 24 sperm candles. The Scotch parrot coals are very various

in quality, yielding from 8000 up to 13,000 cubic feet per ton, varying in illuminating power from 16 to 35 candles. As a general rule, the parrot coals which yield the greatest quantity of gas, yield also gas of the highest illuminating power.

In the process of distillation, gas, tar, and ammoniacal liquor come off together, and are separated by the action of the apparatus employed—a large residuum of coke remains in the retort. The gas consists of a mixture of heavy carburetted hydrogen (olefiant gas), specific gravity, 985; heavy hydro-carbon vapours of various kinds; light carburetted hydrogen, specific gravity, 555; sulphuretted hydrogen, specific gravity, 1191; sulphide or sulphuret of carbon in minute quantity; carbonic oxide, specific gravity, 972; carbonic acid, specific gravity, 1524.

The value of coal-gas depends on the proportion of olefiant gas and heavy hydro-carbons which it contains. Great attention is required in heating the retorts; if their temperature be too low, the tar and

liquor are increased in quantity, and the gas diminished in quantity and deteriorated in quality. If the temperature be too high, the olefiant gas is decomposed, and light carburetted hydrogen formed. While different parts of the apparatus necessary for producing, purifying, storing, and sending out the gas are capable of many variations in size, form, and construction, the order in which they come into use is almost invariable. First there are the *retorts*, *ascension* and *dip pipes*, *hydraulic main*, then the *tar-well* and *condenser*, the *exhauster*, the *washer* or *scrubber*, the *purifier*, the *station-meter*, the *gas-holder*, and the *governor*—the parts printed in italics being indispensable. Besides the above, valves of various forms, simple and complicated, are employed. These, in some of their arrangements, display great ingenuity. Water-traps also have to be applied for collecting and removing the water and tar which condense in the pipes. The annexed wood-cut shews an arrangement common in small gas-works.

ELEVATION OF GAS-WORKS.

Retorts, &c.

Tar Well

Condenser.

Washer.

Dry-Lime Purifier.

The retorts are now generally made of fireclay, though cast-iron retorts are still frequently to be met with. They are made D-shaped, cylindrical, kidney-shaped, and elliptical. The sizes most common are from 6 to 9 feet in length, and from 12 to 20 inches in diameter. In large works, two 9-foot lengths are joined together, forming one retort 18 feet long, with a mouth at each end—a mode of construction which is found to possess considerable advantages. The retort is built horizontally into an arched oven, in such a manner as to be equally heated throughout from a furnace beneath. From one to seven retorts, and sometimes a greater number, are set in the same oven. The open mouth-piece of the retort is of cast iron, and projects outwards from the front wall of the oven sufficiently far to admit between the mouth and the front of the oven, an opening to which the ascension-pipe is connected for conveying the gas to the hydraulic main. When the coal to be distilled is introduced into the retort, the mouth is closed with a lid, which is kept tight by a luting of clay or other material round the edge, and made fast with a screw.

The hydraulic main is a large pipe made of thick plate or cast iron. It is first about half filled with water, which in the course of a short time is entirely displaced by the liquid product of distillation. The dip-pipes, which are the continuation of the ascension-pipes, dip into the liquid through which the gas bubbles up into the upper portion of the hydraulic main. The gas and liquid come off at the end of the hydraulic main, and flow together

till they reach the tar-well, into which the liquid, by its greater gravity, falls. The liquid consists of tar and ammoniacal water. These are withdrawn from the tar-well, and become the raw material from which other products are manufactured. From the tar, naphtha, pitch-oil, pitch, and coke are obtained; and from the water, salts of ammonia are prepared. The tar and ammoniacal water being of different densities are easily separated by being allowed to settle in a vessel. See GAS-TAR, NAPHTHA, AMMONIA, SAL-AMMONIAC, &c. When a retort is opened for withdrawing the exhausted charge of coal and renewing it, the pressure of the gas on the hydraulic main forces the liquid to ascend the dip-pipe, and thus seals it against the gas in the hydraulic, which, but for this, would rush up the dip-pipe, descend the ascension-pipe, escape and ignite at the open mouth of the retort. In the tar-well there is also a dip-pipe, inserted into a deep vessel, to prevent the gas from entering the well. A similar contrivance is resorted to wherever it is necessary to introduce or draw off liquids at any part of the apparatus. The tar-well must be placed so low, that all the liquid in the pipes leading to it from the hydraulic main, and from it to the condenser, must incline towards it.

The simplest form of condenser consists of a series of upright pipes, each pair being connected at the top by an arch pipe. These are erected upon a horizontal chest, the top of which has an opening into the bottom of each upright pipe. Immediately under the centre of each arch pipe, a plate descends

from the top of the chest, and reaches to within a few inches of the bottom. When in operation, the chest is always filled with liquid to such a height, that these plates dip into it, and prevent the gas from passing through the chest horizontally. When admitted into the chest, the gas finds no exit but by ascending the first upright pipe; and, passing over the arch, it descends to the chest again through the second upright pipe. There being no dip-plate between the second and third upright pipes, the gas ascends the third pipe and descends the fourth, and so on through the condenser. The upright pipes are kept cool by exposure to the atmosphere, and sometimes a thin stream of water is caused to flow over them. As the gas ascends and descends, cooling rapidly in its passage, the liquid which has been carried along in a state of vapour, condenses, and falls into the chest, from which it is conveyed back by an overflow-pipe to the tar-well.

The exhauster, when used, is now the next part of the apparatus. It is a species of pump, driven by steam-power, and is made in various forms, both direct-acting and rotary. It serves the purpose of relieving the retorts of the resistance or pressure, created in the passing of the gas through the apparatus, and in raising the gasholder. The use of the exhauster greatly lessens the deposit of carbon in the retorts in the form of graphite, and is attended with other important advantages.

At this stage of the process, the liquid products have been separated from the gaseous. A portion of the ammonia and the sulphuretted hydrogen and carbonic acid have still to be removed. As yet, there are no means practically applicable for the removal of the sulphide of carbon; but the quantity produced is so minute as to be uninjurious, and sufficient ammonia remains in the gas to form the harmless salt sulphate of ammonia as the product of combustion. To remove ammonia from the gas, the washer or scrubber is used. In the washer, the gas is forced to pass through water to a depth of several inches, or through a solution containing an ingredient with which the ammonia will combine. The scrubber, which may be used instead of the washer, is an upright vessel, in which the gas is made to pass through brushwood, or layers of small stones, or coke, through which water may be made to percolate.

There are two kinds of purifiers—the wet and the dry. Either may be used separately, or they may be used in succession. Lime is the purifying material which is most effective; a preparation of the oxide of iron, however, is rapidly coming into general use. Lime is used in the wet purifier in the form of cream of lime. The wet purifier is a cylindrical vessel, into which the gas is introduced through a wide pipe, which descends through the centre of the vessel, and is furnished with a very broad flange on the lowest part. The vessel is filled with the cream of lime to the height of several inches above the flange of the wide pipe. The gas enters through the wide pipe, passes under the flange, and upwards through the cream of lime. The cream of lime is kept in agitation by revolving arms. Two or more of these vessels must be used in succession, in order effectually to remove the sulphuretted hydrogen. The dry purifier is a square or oblong vessel containing a series of perforated trays, on each of which the purifying material is spread. Slacked lime (in the form of dry hydrate) is used in this purifier in layers of from $2\frac{1}{4}$ to $3\frac{1}{4}$ inches on each tray. The lime absorbs the sulphuretted hydrogen, a portion of the ammonia, and the carbonic acid. When saturated, it is removed, and the vessel is refilled with fresh material. The refuse lime is extensively used as a manure. When the oxide of iron is employed

as the purifying material, the preparation is spread in the same manner as the lime, but to a much greater thickness. When by the absorption of sulphuretted hydrogen, the oxide of iron has become sulphuret of iron, it is taken out, and by exposure to the atmosphere, it is reconverted into oxide, and can be used again and again. A great recommendation for the use of the oxide of iron is the abatement of the annoyance caused by the unpleasant smell of the refuse lime. When oxide of iron is used, a separate lime purifier is necessary for removing the carbonic acid. A narrow chamber, nearly full of water, runs round the upper edge of the dry purifier; into this chamber the sides of the cover, which is of sheet-iron, are let down, and the gas is thus prevented from escaping.

After passing the purifier, the gas, which is now fit for use, is measured by the station-meter, an instrument similar in principle to the consumers' meter, afterwards described. It is then conveyed to the gasholder, to be stored and issued as required.

The gasholder is an inverted cylindrical vessel of sheet-iron, placed in a tank of cast iron, stone, or brick containing water. A pipe ascends from the bottom of the tank through the water, to admit the gas to the space between the surface of the water and the crown of the gasholder. Another pipe descends through the water and the bottom of the tank, for the issue of the gas to the main-pipe. The water is for the purpose of retaining the gas within the vessel. The buoyancy of the gas raises the gasholder, and the weight of the gasholder, or such part of it as is not taken off by balance-weights, impels the gas through the pipes. When balance-weights are necessary, they are attached to the edge of the crown of the gasholder by long chains, which pass over pulleys on the top of columns which serve also to guide the motion of the vessel in rising and falling. Gasholders are constructed of all sizes up to 200 feet in diameter, and are made to contain quantities up to two and a half millions of cubic feet. In large establishments, telescopic gasholders are used, and economy of space and cost are thereby effected—two concentric gasholders being

Telescope Gasholder.

contained in one tank. The outer vessel of a telescope gasholder has no crown. The upper edge is turned first inwards and then downwards, forming an inverted hollow chamber. The under edge of the inner vessel again is turned outwards and upwards, forming a hollow chamber, which, when the vessel rises out of the tank, will be full of water. The

inner side of the inverted chamber, round the top of the outer vessel, fits into the inside of the chamber round the bottom of the inner vessel, and enters it when that vessel has nearly ascended to the top of the tank. The water in the chamber retains the gas, and the two vessels then rise together. The inner vessel, it will be observed, ascends first; both then ascend and descend together, till the outer vessel has reached the bottom of the tank, on which it rests, and the inner vessel then also descends into the tank. Three gasholders, or lifts, as they are termed, are occasionally placed in the same tank.

Before reaching the main-pipes, the pressure of the gas is regulated by the governor. In small establishments, the governor is very frequently dispensed

the main; and where this cannot be attained, provision should be made for drawing off water.

Gas-fittings.—The small pipes for fitting up the interiors of houses are either of wrought iron or of soft metal. To ensure permanent efficiency, it is of the utmost importance that these pipes should be *capacious*; they should be laid *evenly*, with an inclination towards the meter; and where the inclination is materially disturbed, a box should be provided for the collection and removal of water.

Gas for street lighting is usually supplied by contract, a specified burner being used, and the lights being lighted and extinguished at stipulated hours. Lights in private establishments were originally charged for on the same system. The uncertainty of such a mode of charge directed the attention of gas-engineers to the construction of meters at a very early period. Accordingly, in 1816, Mr Clegg took out his first patent for the wet gasmeter, which, as subsequently improved by Malam, Crosley, and others, came into general use about the year 1822. Dry gasmeters are now extensively manufactured on a principle first patented by Mr A. A. Croll, a gentleman who has also patented various modifications of the apparatus and processes used in the manufacture and purification of gas.

The wet gasmeter consists of a hollow circular case, somewhat more than half filled with water. The measurement is made by the cylinder, a hollow drum or wheel, which revolves on a horizontal axis inside the case, the elasticity of the gas supplying the motive-power. The cylinder is divided into four chambers by partitions running in a slanting direction from back to front, and presenting a

Gas Governor.

with, and the pressure adjusted with sufficient nicety by the regulation of the outlet valve. The governor consists of a small gasholder, the inlet-pipe to which is placed in the centre of the tank, and terminates with a plate having a circular orifice in its centre. In this orifice hangs a cone, which is attached to the crown of the small holder. When the gas is issuing slowly, the holder rises, taking with it the cone, and so restricting the orifice by which the gas enters. When the gas issues rapidly, the holder falls, and with it the cone, thereby enlarging the inlet.

The gas is conveyed from the works by main-pipes of cast iron, to which branch or service pipes are connected wherever a supply is wanted. The main-pipes require to be skilfully arranged with respect to size, carefully jointed, and laid with as few changes in their inclination as possible; but as such changes are unavoidable, it is necessary to provide for the removal of water, which, flowing along with the gas in the form of vapour, condenses in the pipes, and lodges at low points. For this purpose, a vessel, similar in construction to the tar-well, is connected to the main-pipe, and the water is removed by a pump. When little condensation is anticipated, and when there is no risk of the water affecting the flow of the gas, a small pipe merely is attached to the main, with a stop-cock to run off the water. The service-pipes should incline towards

Wet Meter—front box open:

A, entrance pipe; B, valve chamber; C, float, with valve on the upper end; D, surplus or waste-water box.

section of a four-threaded Archimedean screw. A convex cover is fixed on one end of the cylinder. This cover has an opening in the centre, which admits the pipe by which the gas enters the cylinder; the opening being below the surface of the water, so as to be sealed by it. The pipe, after entering the opening, is turned up, so that its mouth is above the water. The gas thus admitted within the cover, finds its way through a slit into one of the four chambers into which the cylinder is divided. The chamber which first comes into action is at the moment almost entirely under the water. The gas presses between the water and the partition of the chamber, and, in raising the partition, turns the cylinder on its axis, and brings the chamber above the water, filling it at the same time. The outlet slit of the chamber is on the side of the cylinder

opposite to the inlet slit, and is open to the case of the meter. It is not, however, directly opposite to the inlet slit, but is so arranged that it remains

sealed under water till the chamber is completely filled with gas, by which time the revolution of the cylinder has brought the inlet slit of the next chamber above the water, and it is ready to receive the gas. The filling of the next chamber carries round the one already filled, causes its descent into the water as it revolves, and completely expels the gas by the outlet slit. Two chambers only can be in action at one time. These chambers are made with great accuracy, and are liable to no variation but the enlargement caused by the evaporation of the water and the

consequent depression of the water-line. On the

front of the case of the meter is placed a box, into which the axis of the cylinder extends, having a spiral worm-wheel on its end. The worm-wheel communicates motion to an upright spindle, which again moves the train of wheels by which the handles of the index are worked. The front box also contains the filling and overflow pipes for the supply and adjustment of the water, the entrance-chamber by which the gas is admitted, and in which the float-valve is placed. This valve is supported and kept open by a float which descends, closes the valve, and shuts off the gas when the water is depressed too much.

An act of the British legislature has recently been passed, according to which all gasmeters must be so constructed as not to register more than 2 per cent. in favour of the seller, and 3 per cent. in favour of the purchaser of gas. Thus allowing 5 per cent. for variation caused by the depression of the water-line on wet gasmeters. All meters fixed since the act came into operation must bear the seal of an inspector appointed under the act. Previous to the passing of this act, wet gasmeters were made so that when the water-line was properly adjusted, they could not measure more than $2\frac{1}{4}$ per cent. in favour of the seller, but they would register from 8 to 12 per cent. in favour of the purchaser before the water-line was sufficiently depressed to close the float-valve. In the arrangement adopted by Croxley, there was a defect which was unfortunately adhered to by many meter-makers in England, though it was abandoned by most of the makers in Scotland. This defect, known as 'the high spout,' arose from the pipe or spout which receives the gas in the front box, and conveys it into the cylinder, being made to project considerably above the water-line. This was intended to prevent the consumers of gas from being subjected to the inconvenience of their lights being rendered unsteady, or being extinguished by water coming over the edge of the spout and lodging in the bend which enters the cylinder; but if, in supplying water to the meter, the overflow-pipe which adjusts the water-line were closed, by the replacing of the plug before all the surplus water had run off, too much water would be contained in the meter, and its measuring capacity would consequently be restricted to the prejudice of the purchaser; and this having been ascertained to have

occurred in various instances, much dissatisfaction was the natural result. The provisions of the act regulating measures used in sales of gas enforce the making of wet gasmeters with 'the low spout,' and consequently remove this objection entirely. Much skill and ingenuity have, since the passing of the act, been brought to bear on the construction and arrangement of wet gasmeters, in order to lessen, and, if possible, remove the risk of the float-valve closing more frequently than formerly, which it will be apt to do owing to the limitation of the descent of the water by the restriction of the variation of the measurement to 3 per cent. instead of from 8 to 12 per cent. against the seller.

The dry gasmeter possesses some advantages,

Dry Meter—front view open.

which, were it in other respects equally esteemed with the wet meter, would give it the preference. Once adjusted, it gives no further trouble; it is not liable to derangement in frosty weather; and, in passing through it, the gas takes up no additional moisture to increase the risk of annoyance from deposit of water in the pipes. But doubts are entertained by many of the durability of the machine as an efficient and correct measure. The meter is made in various forms, and consists of chambers separated from each other by partitions; generally there are two, but some makers use three chambers. Each chamber is divided into two parts by a flexible partition which moves backwards and forwards, its motion being regulated by valves beautifully contrived for the purpose. The meter bears some resemblance to a double or triple steam-engine. Following out this resemblance, Mr Croll thus describes his meter 'It consists of a cylinder divided by a plate in

the centre, into two separate cylindrical compartments, which are closed at the opposite ends by metal discs; these metal discs serve the purpose of pistons, and they are kept in their places by a kind of universal-joint adapted to each; the space through which the discs move, and, consequently, the means of measurement, is governed by metal arms and rods, which space, when once adjusted, cannot vary. To avoid the friction attending a piston working in a cylinder, a band of leather is attached, which acts as a hinge, and folds with the motion of the disc; this band is not instrumental in the measuring, so that if it were to contract or expand, the registering of the meter would not be affected, inasmuch as it would only decrease or increase the capacity of the hinge, the disc still being at liberty to move through the required space; the leather is also distributed in such a manner, being curved, and bending only in one direction, that it prevents any wrinkles or creases forming, and renders it therefore much more durable. The arrangement of the valves and arms are somewhat different to that of a steam-engine, although similar in principle.

Consumers of gas should bear in mind, that the purpose of the meter is to inform them how much gas they are expending; and that while the seller of gas cannot visit it but at long intervals, the purchaser may from day to day, if he pleases, ascertain the quantity which has passed through the meter, and so detect irregularity or waste, which, if allowed to go on, would no doubt be put down to error on the part of the seller of gas.

Gas-burners.—The burner made on the argand principle is still the best when carefully used, but it is expensive, somewhat troublesome to keep clean, and involves outlay for glasses from time to time. Jets and batwings have, consequently, almost supplanted it. These burners are now made by machinery at very low prices, so that to change them when out of order costs little, and is easily done. They are also very easily cleaned. Jets are of two kinds—cockspurs and union-jets. The cockspurs are pierced with one or more straight holes; the union-jets are pierced with two holes at an angle to each other, so that the streams of gas issuing from them impinge on each other, and produce a flat flame. Batwings are made with a clean slit across the head of the burner. Gas containing a great quantity of carbon requires burners with smaller apertures than gas containing little carbon, because when emitted too freely, the carbon does not come into contact with a sufficient quantity of oxygen, and the flame smokes: again, when the gas is emitted in too small a quantity, the flame becomes blue, and its illuminating power is diminished, because the carbon

comes too rapidly into contact with oxygen. The light is emitted by the carbon when suspended for an instant in the flame in an incandescent state, and the flame which is capable of suspending the largest proportion of carbon in a state of incandescence, ultimately consuming the whole of it, will give the most powerful light from the smallest quantity of gas. Accordingly, an opaque yellowish flame, which is just at the smoking point, is more economical than a bluish-white flame for lighting purposes.

There are many contrivances for improved burners and improved modes of using gas. Of these it is enough to mention the sun-lights introduced by Mr King of Liverpool. These consist of a ring of union-jets, placed horizontally and set on the base of a cone which is passed through the ceiling, and conveys away the products of combustion through a flue, thus serving both for lighting and ventilating the apartments in which they are used.

Regulators.—The object of these instruments is to restrict the supply of gas when superabundant, and it should be noticed that the supply requires to be so before any advantage can result from the use of them. A conical valve, operating by the pressure of the gas in a manner similar to the governor at the gas-works, is in general the acting part of the apparatus.

The impurities which should be removed in the manufacture of coal-gas are sulphuretted hydrogen, ammonia, and carbonic acid. The presence of sulphuretted hydrogen is detected by allowing a stream of the gas to play on a paper wetted with a solution of acetate of lead, the test-paper is blackened if the deleterious gas be present. Ammonia is detected by allowing the gas to play on paper stained yellow with turmeric. Ammonia changes the yellow to brown. The presence of carbonic acid can be ascertained by causing the gas to bubble through lime-water. If carbonic acid be present, it combines with the lime, and the water becomes milky.

The value of gas for lighting depends on its illuminating power, which again mainly depends on the proportion of olefiant gas and heavy hydrocarbons contained in the mixture. The specific gravity of the gas would be a complete test of the illuminating power, were it first ascertained that no deleterious gases were contained in the mixture. The chlorine and bromine tests, which are applied by bringing the gas into contact with either of these substances in a graduated tube, also require that the absence of deleterious gases be ascertained. Chlorine and bromine condense the olefiant gas and heavy hydrocarbons, and the proportion of them present is ascertained by the proportion of the gas which is condensed.

Gas-photometer.

The most practical mode of determining the illuminating power is by the use of the Bunsen photometer, introduced into this country by Dr Lyon Playfair, and adapted by Mr King of Liver-

pool. At one end of a straight bar of wood, a gas-burner is mounted; on the other end, a candlestick. These are so placed, that when lighted, there are exactly 100 inches between the centres of the lights.

The bar is correctly graduated to shew how many times the one light exceeds the other. A circular disc of paper made semi-transparent, excepting a spot in the centre, which is left opaque, is placed at right angles across the graduated bar on a stand which slides along the bar. When the disc is moved into a position where the opaque spot is invisible, the lights are equal—the disappearance of the spot being caused by the light transmitted by the semi-transparent part of the disc being equal to that reflected by the opaque part. The figures immediately below the disc indicate the power of the light. It is usual to compare a burner consuming five feet per hour with a sperm candle consuming 120 grains per hour, and when the quantities consumed during an experiment are not exactly in these proportions, the results are rectified by calculation.

As has been stated, the illuminating power of coal-gas may vary from ten sperm candles up to nearly forty, though it is more than probable that either extreme is unknown to consumers; the cost of production, however, does not vary in the same ratio with the value of the gas, it being affected by totally independent causes, and these causes are so various, that the cost can hardly be the same in any two places. Another difficulty in contrasting the price of gas in different places, arises from the unavoidable variation in the quantity accounted for, the loss sustained under the head of condensation, leakage, bad debts, and waste, varies from 10 up to 30 per cent. on the whole quantity made; and though when this loss is excessive, the remedy should, to a certain extent, be in the power of the manufacturer, yet there is a considerable range within which the loss may vary owing to local and peculiar circumstances which the manufacturer cannot control. The price of gas being dependent on the cost of production and distribution, rather than on the illuminating power, and the changes in the former being less than the variations in the latter, gases of high illuminating power are more economical than gases of low illuminating power.

The economy of gas for lighting purposes will be apparent when it is considered that 50 feet of gas, consumed in a burner at 5 feet per hour, will last 10 hours; while a sperm candle of six to the pound, and burning 120 grains per hour, will only last 9·722 hours. Assuming, however, that both will last 10 hours—a view which is in favour of the candle—1000 cubic feet will last as long as 20 candles; therefore, with an illuminating power of 15 candles, it will give an amount of light equal to 300 candles, or 50 lbs., which at 2s. per pound would cost £5; at 20 candles it would equal 400, or 66⅔ lbs., costing £8, 13s. 4d.; at 25 candles it would equal 500, or 83⅓ lbs., costing £8, 6s. 8d.; at 30 candles, it would equal 600, or 100 lbs., costing £10.

Mr Rutter, author of a useful pamphlet titled *Advantages of Gas in Private Houses* (Parker and Son, West Strand), gives the following table, the experiments from which it is deduced having apparently been made with 12 or 14 candle-gas at 6s. per 1000 feet.

for equal quantities of light, which, however, is not the measure of economy, just because no one is contented to take no more light from gas than from other modes of lighting; and second, because the gas-lights being fixed, more light is requisite in order to compensate the loss of the convenience afforded by a movable light. Five feet per hour of 15 candle-gas will fully supply the place of a pair of sperm candles, costing 8d. for 10 hours' light; while the gas at 6s. per 1000 feet would only cost 3d. for the same time, and would yield a light $7\frac{1}{2}$ times as great.

The use of gas for heating and cooking is becoming extensive. Its great recommendations are facility of regulation, readiness of application, and perfect cleanliness. In roasting by gas, the juices are retained in the meat to a greater extent than by the ordinary process; while in all the operations, the heat can be regulated with so much nicety, as greatly to aid the cook in presenting the food in the most wholesome and agreeable condition.

Besides brilliancy of light, safety and cleanliness attend the use of gas. Explosions under ordinary circumstances are hardly possible—the escape of gas is quite disagreeably perceptible by the smell when there is one three-thousandth part present in the atmosphere; and there can be no explosion unless with, at the least, 200 times that quantity, or 1 part in 15. Such accumulations will, and do undoubtedly, take place in confined situations, but ordinary precaution in avoiding the use of a light will avert the risk of accident. Gas, having a tendency to ascend, escapes near the ceiling of an apartment are more likely to form an explosive mixture than escapes occurring low down. Repeated accidents have happened through forgetfulness of this. It should be remembered that the situation must be considered a confined one when the gas is prevented from ascending freely. The standard work on gas-lighting is that by the late Samuel Clegg, Jun., son of the inventor of the gasmeter, published by John Weale, London. There is also a smaller work by the same publisher, written by Samuel Hughes, C.E.

GASCOIGNE, SIR WILLIAM, an eminent English judge, belonging to a noble Norman family, was born at Gaythorpe, Yorkshire, in 1350. After studying for the bar, he acquired considerable reputation as a pleader, and in 1398 was made serjeant-at-law. On the accession of Henry IV. in 1399, he was appointed one of the justices of the Court of Common Pleas; and in 1401, was promoted to be chief-justice of the King's Bench. In this high office he distinguished himself both by integrity and ability, and in the older English law reports are many abstracts of his opinions, arguments, and decisions. In July 1403, he was joined with the Earl of Westmoreland in a commission for levying forces against the insurrection of Henry Percy, the celebrated Hotspur. He was also nominated one of the commissioners to treat with the rebels. On this and another memorable occasion, he acted with a courage and rectitude which evinced that he was guided by the true spirit of judicial independence. On the apprehension of Scroop, archbishop of York, he refused, at the command of the king, to sentence that prelate to death as a traitor, because the law gave him no jurisdiction over the life of an ecclesiastic. Henry respected his uprightness, and knighted him the same year. When one of the dissolute associates of the Prince of Wales was arraigned before him for felony, the prince imperiously demanded his release, and on being ordered to leave the court, he rushed furiously up to the bench, and, it is recorded, struck the chief-justice on the judgment-seat. G. immediately

COMPARATIVE COST OF LIGHT FROM CANDLES, LAMPS, AND GAS.

	Quantities and Prices of Candles and Oil.		Quantities and Cost of Gas.	
			Cub. feet.	per 1000.

" " (moulds), . .	1 lb.	0 7	31	0 12
Composite Candles, . .	1 lb.	0 10	25	0 12
Wax " "	1 lb.	2 4	25	0 12
Common Lamp Oil, . . .	1 gall.	5 6	175	1 0
Sperm Oil,	1 gall.	10 0	217	1 3

It must be remarked, that the above prices are

committed him to prison, when the prince, sensible of his misconduct, at once submitted. On being informed of the circumstance, the king thanked God for having given him 'both a judge who knew how to administer the laws, and a son who respected their authority.' G. was called to the first parliament of Henry V., but died the same year, December 17, 1413. He was twice married, and left numerous descendants by both his wives.

GASCON, GASCONNADE. The term *Gascon* is now employed, in the French language, to denote a boaster or braggart, and *Gasconnade* to signify any extravagant or absurd vaunting—the inhabitants of the district once known as Gascony having long been notorious in this respect. An example may be given: a Gascon, on a visit to Paris, was asked by his city-friend what he thought of the colonnade of the Louvre. His reply was: 'Ah, it's not bad; it resembles pretty closely the back part of the stables at my father's castle!' There are in French, volumes filled with the original sallies of these humorous boasters.

GA'SCONADE, a river of North America, rises in the south of the state of Missouri, and, after flowing north-east for 250 miles, joins the river Missouri about 40 miles below Jefferson City. It flows through a hilly country, covered with forests of pine and other timber, and rich in picturesque scenery. Great rafts of yellow pine lumber are floated down the river annually.

GA'SCONY (Lat. *Vasconia*), formerly a district in the south-west of France, was situated between the Bay of Biscay, the River Garonne, and the Western Pyrenees, and is now included in the departments of Landes, Gers, Hautes Pyrénées, and the southern portions of Haute Garonne, Tarn-et-Garonne, and Lot-et-Garonne. It derived its name from the Basques or Vasques, who, driven by the Visigoths from their own territories on the southern slope of the Western Pyrenees, crossed to the northern side of that mountain-range in the middle of the 6th c., and settled in the former Roman district of Novempopulana. In 602, after an obstinate resistance, the Vasques were forced to submit to the Franks. They now passed under the sovereignty of the Dukes of Aquitania, who for a time were independent of the crown, but were afterwards conquered by King Pepin, and later by Charlemagne. Subsequently it became incorporated with Aquitania (q. v.).

GASES, GENERAL PROPERTIES OF. The term gas—which is probably derived from the German word *Geist*, spirit—was employed by the older chemists to designate any kind of air or vapour. Macquer (q. v.) was the first chemist who limited the term gas to such elastic fluids as had not been rendered liquid or solid by a reduction of temperature. The only substances that gases are liable to be confounded with are vapours; but there is this essential difference between them, that the former are invariably æiform at ordinary temperatures and atmospheric pressures, while the latter under these conditions are solid or liquid, and only assume a vaporous or apparently gaseous form at relatively high temperatures. Thus oxygen, hydrogen, nitrogen, chlorine, &c., are true gases; while water, sulphur, iodine, &c., when heated to certain definite points, become transformed into vapours.

Their perfect elasticity is one of the most important physical peculiarities of gases. Within the limits of all ordinary experiments it is generally true that 'the volume of a gaseous body is inversely as the compressing force.' See **MARIOTTE'S LAW**.

In consequence of their extreme elasticity, gases

exhibit an entire absence of cohesion among their particles, and in this respect they differ essentially from liquids. A vessel may be filled either partially or completely with a liquid, and this liquid will have a definite level surface or limit. With gases, it is otherwise; they always perfectly fill the vessel that contains them, however irregular its form. Instead of cohesion, there is a mutual repulsion among their particles, which have a continual tendency to recede further from each other, and thus exert a pressure in an outward direction upon the sides of the vessel in which the gas is enclosed. This outward pressure is greater or less according as the elasticity of the gas is increased or diminished. Experimental proofs of the facts mentioned in this and the preceding paragraph may be found in Miller's *Chemical Physics*, in the first volume of Jamin's *Cours de Physique*, or in any standard work on Physics.

Dalton long ago remarked that 'there can scarcely be a doubt entertained respecting the reducibility of all elastic fluids, of whatever kind, into liquids; and we ought not to despair of effecting it at low temperatures and by strong pressure exerted upon the unmixed gases.' Various chemists, amongst whom we must especially mention Faraday, have accomplished all that Dalton foretold, and various gases can now be exhibited not only in the liquid but in the solid form. It occurred to Faraday, who has led the van in these investigations, that the most probable mode of obtaining gases (or rather what, under ordinary circumstances, would be gases) in the liquid state, would be to generate them under strong pressure. When thus produced in strong bent glass tubes, they continued liquid at low temperatures while the pressure was maintained; but on removing the pressure (breaking the tube), they instantly passed into the gaseous state. In his Memoir, published in the *Philosophical Transactions* for 1823, he announces that he has succeeded in liquefying chlorine, euchlorine (a yellow explosive gas discovered by Davy, and consisting of a mixture of chlorine and chloro-chloric acid), sulphuretted hydrogen, nitrous oxide, cyanogen, ammonia, and hydrochloric, sulphurous and carbonic acids. Since that time, by the joint action of powerful mechanical pressure (sometimes upwards of 50 atmospheres), and extreme cold, the number of liquefiable gases has been so far extended as to include all except oxygen, hydrogen, nitrogen, nitric oxide, and coal-gas; and the following gases have been obtained in a solid form—hydriodic acid, hydrobromic acid, sulphurous acid, sulphuretted hydrogen, carbonic acid, cyanogen, ammonia, euchlorine, fluoride of silicon. The ammonia and sulphuretted hydrogen, when solidified, each furnished a white translucent mass, like fused nitrate of ammonia; euchlorine gave a transparent orange-coloured crystalline solid; while the other liquefied gases that were susceptible of solidification by the application of intense cold, furnished colourless transparent crystalline masses like ice.

Oxygen remained gaseous under a pressure of 27 atmospheres at a temperature of -166° , and a pressure of 58.5 atmospheres at -140° was equally ineffectual in producing its liquefaction. Nitrogen and binoxide of nitrogen resisted a pressure of 50 atmospheres; with carbonic oxide, a pressure equivalent to that of 40 atmospheres, with coal-gas, one of 32, and with hydrogen, one of 27 atmospheres was applied without effecting the liquefaction. In all these experiments, the temperature was maintained at -166° . Owing to the superior diffusiveness of the lighter gases, such as hydrogen, the apparatus began to leak at comparatively low pressures, and thus a limit was placed to the amount of pressure that could be applied to them.'

GASES.

As a point of historical interest, we may mention that many years before the publication of Faraday's earliest researches on this subject, sulphurous acid gas had been liquefied by Monge and Clouet, ammonia by Guyton Morveau, and arseniuretted hydrogen by Stromeyer, by the simple application of cold, without any increased pressure.

The expansion and contraction of gases by changes of temperature is treated of under **HEAT**.

The process of intermixture in gases, and the movements of these substances generally, have been very carefully studied by Faraday, Döbereiner, Mitchell, Bunsen, and especially Graham. These movements are usually considered under four heads, viz.: 1. *Diffusion*, or the intermixture of one gas with another; 2. *Effusion*, or the escape of a gas through a minute aperture in a thin plate into a vacuum; 3. *Transpiration*, or the passage of different gases through long capillary tubes into a rarefied atmosphere; 4. *Osmosis*, or the passage of gases through diaphragms.

In the article *Diffusion* (q. v.), the general principles of this kind of movement in gases are sufficiently explained, and we shall merely make one or two supplementary remarks, chiefly with the view of rendering the following table more intel-

ligible. Graham's experiments with the simple diffusion-tube shew (see Graham's Memoirs in the *Transactions of the Royal Societies of London and Edinburgh*, or Miller's *Chemical Physics*) that the diffusiveness or *diffusion volume* of a gas is in the inverse ratio of the square root of its density; consequently, the squares of the times of equal diffusion of the different gases are in the ratio of their specific gravities. Thus, the density of air being taken as the standard of comparison at 1, the square root of that density is 1, and its diffusion volume is also 1; the density of hydrogen is 0.0692, the square root of that density is 0.2632, and its diffusion volume is $\frac{1}{0.2632}$, or 3.7994; or, as actual experiment shews, 3.83—that is to say, if hydrogen and common air be placed under circumstances favouring their mutual diffusion, 3.83 volumes of hydrogen will change place with 1.00 of air. The following table gives: 1. The density; 2. The square root of the density; 3. The calculated, and 4. The observed velocity of diffusion or diffusiveness of several important gases; the numbers in the last column, headed 'Rate of Effusion,' being the results obtained by experiment upon the rapidity with which the different gases escape into a vacuum through a minute aperture about $\frac{1}{10}$ of an inch in diameter.

Gas.	Density.	Square Root of Density.	Calculated Velocity of Diffusion.	Observed Velocity of Diffusion. Air = 1.	Rate of Effusion.
Hydrogen,	0.06926	0.2633	3.7994	3.83	3.613
Light Carburetted Hydrogen,	0.559	0.7476	1.3375	1.344	1.322
Carbonic Oxide,	0.9678	0.9837	1.0165	1.0149	1.0123
Nitrogen,	0.9713	0.9859	1.0147	1.0143	1.0164
Olefant Gas,	0.978	0.9890	1.0112	1.0191	1.0198
Binoxide of Nitrogen,	1.039	1.0198	0.9908		
Oxygen,	1.1056	1.0515	0.9510	0.9487	0.950
Sulphuretted Hydrogen,	1.1912	1.0914	0.9168	0.95	
Protoxide of Nitrogen,	1.537	1.2397	0.8092	0.83	0.834
Carbonic Acid,	1.53901	1.2395	0.8087	0.812	0.821
Sulphurous Acid,	2.947	1.4991	0.6671	0.69	

'The process of diffusion,' says Professor Miller, 'is one which is continually performing an important part in the atmosphere around us. Accumulations of gases which are unfit for the support of animal and vegetable life are by its means silently and speedily dispersed, and this process thereby contributes largely to maintain that uniformity in the composition of the aerial ocean which is so essential to the comfort and health of the animal creation. Respiration itself, but for the process of diffusion, would fail of its appointed end, in rapidly renewing to the lungs a fresh supply of air, in place of that which has been rendered unfit for the support of life by the chemical changes which it has undergone.'

A reference to the last two columns of the above table shews that, within the limits of experimental errors, the rate of effusion of each gas coincides with its rate of diffusion.

Graham's experiments shew that the velocity of *transpiration* (the term which that chemist applied to the passage of gas through long capillary tubes) is entirely independent of the rate of diffusion, or of any other known property. It varies with the chemical nature of the gas, and is most probably 'the resultant of a kind of elasticity depending upon the absolute quantity of heat, latent as well as sensible, which different gases contain under the same volume; and therefore will be found to be connected more immediately with the specific heat than with any other property of gases.' Oxygen is found to have the lowest rate of transpiration. Taking its transpiration velocity at 1, that of air is 1.1074; of nitrogen, 1.141; of carbonic acid,

1.369; of sulphuretted hydrogen, 1.614; of ammonia, 1.935; of olefant gas, 1.980; and of hydrogen, 2.288.

In the passage of gases through diaphragms, the law of the diffusion of gases is more or less disturbed or modified according to the force of adhesion in the material of which the diaphragm is composed; the disturbance being greatest in the case of soluble gases and a moist thin diaphragm, such as a bladder or a rabbit's stomach. For details on this subject we must, however, refer to the article **OSMOSIS**.

All gases are more or less soluble in water and other liquids. Some gases, as, for example, hydrochloric acid and ammonia, are absorbed by water very rapidly, and to a great extent, the liquid taking up 400 or 600 times its bulk of the gas; in other cases, as carbonic acid, water takes up its own volume of the gas; whilst in the case of nitrogen, oxygen, and hydrogen, it does not take up more than from $\frac{1}{15}$ to $\frac{1}{10}$ of its bulk. 'As the elasticity of the gas,' says Professor Miller, 'is the power which is here opposed to adhesion, and which at length limits the quantity dissolved, it is found that the solubility of each gas is greater, the lower the temperature, and the greater the pressure exerted upon the surface of the liquid. Dr Henry found that at any given temperature the volume of any gas which was absorbed was uniform, whatever might be the pressure; consequently, that the *weight* of any given gas absorbed by a given volume of any liquid at a fixed temperature, increased directly with the pressure. If the pressure be uniform, the quantity of any given gas absorbed by a given liquid is also uniform for each temperature; and the numerical

GASES.

expression of the solubility of each gas in such liquids, is termed its *coefficient of absorption* or of *solubility*, at the particular temperature and pressure, the volume of the gas absorbed being in all cases calculated for 32° F., under a pressure of 29·92 inches of mercury. Thus, 1 volume of water at 32°, and under a pressure of 29·92 inches of the barometer, dissolves 0·04114 of its volume of oxygen; and this fraction represents the coefficient of absorption of oxygen at that temperature and pressure. Similarly, the coefficient of absorption of common air is 0·02471. In consequence of this solubility of the air, all water contains a certain small proportion of it in solution; and if placed in a vessel under the air-pump, so as to remove the atmospheric pressure from its surface, the dissolved gases rise in minute

bubbles. Small as is the quantity of oxygen thus taken up by water from the atmosphere, it is the means of maintaining the life of all aquatic animals. If the air be expelled from water by boiling, and it be covered with a layer of oil, to prevent it from again absorbing air, fish or any aquatic animals placed in such water quickly perish. Even the life of the superior animals is dependent upon the solubility of oxygen in the fluid which moistens the air-tubes of the lungs, in consequence of which this gas is absorbed into the mass of the blood, and circulates through the pulmonary vessels.' -

The following table, drawn up from the researches of Bunsen and Carius, shews the solubility of some of the most important gases, both in water and alcohol:

Gas.	Volume of each Gas dissolved in 1 Volume of Water.		Volume of each Gas dissolved in 1 Volume of Alcohol.	
	At 32 Degrees F.	At 50 Degrees F.	At 32 Degrees F.	At 50 Degrees F.
Ammonia,	1049·60	737·2		
Hydrochloric Acid,	504·9	458·0		
Sulphurous Acid,	68 861	48·544	328·63	144·55
Sulphuretted Hydrogen, . . .	4·3706	3·2336	17·181	9·539
Chlorine,	Solid	2·368		
Carbonic Acid,	1 7967	1·002	4·3295	3·1993
Protoxide of Nitrogen, . . .	1·3063	0·0778	4·1780	3·2678
Olefiant Gas,	0·2563	0·1615	3·5950	2·8625
Binoxide of Nitrogen, . . .			0·31606	0·27478
Marsh Gas,	0·05449	0·03909	0·32259	0·46380
Carbonic Oxide,	0·03387	0·02432	0·30443	0·20443
Oxygen,	0·04114	0·02989	0·28397	0·28397
Nitrogen,	0·02035	0·01478	0·12634	0·12143
Air,	0·02471	0·01795		
Hydrogen,	0·01930	0·01330	0·06925	0·06725

All these gases, with the exception of hydrochloric acid, may be expelled from the water by long-continued boiling.

Gases are not absorbed by all liquids in the same order; for example, naphtha absorbs most olefiant gas, oil of lavender most protoxide of nitrogen, olive oil most carbonic acid, and solution of chloride of potassium most carbonic oxide.

If a mixture of two or more gases be agitated with water, or probably any other liquid, a portion of each gas will be absorbed, and the amount of each so absorbed or dissolved will be proportional to the relative volume of each gas multiplied with its coefficient of solubility at the observed temperature and pressure. As all ordinary liquids exert a greater or less solvent action on gases, a gas that we wish to examine quantitatively should be collected over mercury.

The adhesion of gases to solids next requires notice. Illustrations of this phenomenon perpetually occur. Thus, wood and other solid substances immersed in water or other liquids appear covered with air-bubbles. It is this adhesion of air to the surface of glass tubes which causes the difficulty of obtaining barometers and thermometers completely free from air. It is in consequence of the adhesion of air to their surfaces that many small insects are enabled to skim lightly over the surface of water which does not wet them. A simple method of illustrating this phenomenon is by gently dusting iron filings over the surface of a vessel of water; if we proceed carefully, a considerable mass of the iron may accumulate upon the surface; till, at last, it falls in large flakes, carrying down with it numerous bubbles of air. As the particles of iron are nearly eight times as heavy as water, it was only the adherent air that enabled them to float upon the surface. Closely allied to this adhesion is the remarkable property of condensation which porous bodies,

and especially charcoal, exert on gases. Owing to this property of charcoal—especially freshly burned vegetable charcoal—various gases may be separated from their watery solution by filtration of the latter through it; for example, sulphuretted hydrogen may be removed from water so completely that it cannot be detected either by its well-known odour or by the ordinary tests. Saussure found that 1 volume of freshly burned box-wood charcoal absorbed 90 volumes of ammonia, 85 of hydrochloric acid, 65 of sulphurous acid, 55 of sulphuretted hydrogen, 40 of protoxide of nitrogen, 35 of carbonic acid, 35 of bi-carburetted hydrogen, 9·4 of carbonic oxide, 9·2 of oxygen, 7·5 of nitrogen, 5·0 of carburetted hydrogen, and 1·7 of hydrogen. These results follow an order very nearly the same as that of the solubility of the gases in water.

Stenhouse has investigated the differences in the absorbent power of different kinds of charcoal; the following are his most important results: 0·5 of a gramme of each kind of charcoal being employed, and the numbers in the table indicating in cubic centimetres the quantity of absorbed gas.

Gas Used.	Kind of Charcoal employed.		
	Wood.	Peat.	Animal.
Ammonia,	98·5	96·0	43·5
Hydrochloric Acid,	45·0	60·0	
Sulphurous Acid,	33·5	27·5	17·5
Sulphuretted Hydrogen, . . .	30·0	26·5	9·0
Carbonic Acid,	14·0	10·0	5·0
Oxygen,	0·8	0·6	0·5

So rapid is this action of charcoal, that Stenhouse has proposed to use a respirator filled with it to protect the mouth and nostrils in an infected atmosphere; and the employment of trays of powdered wood-charcoal in dissecting-rooms, in the wards of

lupulæ, and in situations where putrescent animal matter is present, is found to act very beneficially in purifying the air by absorbing the offensive gases. Its use in reference to the filtration of water has been already alluded to.

The determination of the exact specific gravity of the different gases is of great importance in calculating the proportions of the different ingredients of compounds into which they enter; and the whole series of numbers expressing the chemical equivalents or atomic weights of bodies depend upon the accuracy of the determination of the specific gravity of hydrogen and oxygen.

The following table gives the specific gravity and the weight of 100 cubic inches of some of the most important gases at a barometric pressure of 30 inches, and at a temperature of 60°, together with the name of the observer:

Gas.	Specific Gravity. Air = 1.	Weight of 100 Cubic Inches in Grains.	Observer.
Air,	1.0000	30.935	Regnault.
Oxygen,	1.1056	34.203	"
Nitrogen,	0.9713	30.119	"
Hydrogen,	0.0692	2.143	"
Carbonic Acid,	1.5290	47.308	"
Chlorine,	2.5000	76.260	Thomson.
Ammonia,	0.5902	18.003	"
Carburetted Hydrogen,	0.5655	16.944	"
Olefiant Gas,	0.9722	29.652	"
Arsenuretted Hydrogen,	0.5290	16.130	Tromsdorff.
Sulphuretted Hydrogen,	1.1805	36.007	Thomson.
Cyanogen,	1.8065	55.069	Gay Lussac.
Hydrochloric Acid,	1.2847	39.183	Thomson.
Sulphurous Acid,	2.2223	67.777	"

The methods employed for determining the specific gravity of a gas, both by direct observation and by calculation, will be noticed in the article SPECIFIC GRAVITY.

As to the chemical properties of gases, most of the different gases, when pure, can be readily distinguished by some well-marked physical or chemical property. Some are distinguished by their colour, others by their peculiar odour; but several of the most important ones—viz., oxygen, nitrogen, hydrogen, carbonic acid, carbonic oxide, light carburetted hydrogen, olefiant gas, and protoxide of nitrogen—require other means for their discrimination. The distinctive characters of the most important gases are noticed in the articles OXYGEN, HYDROGEN, CHLORINE, &c., and the outlines of the general method of analysing a gaseous mixture are given in a separate article. For further details on the physical and chemical characters of the gases, we must refer to Miller's *Elements of Chemistry*, and especially to the volume on *Chemical Physics*, from which we have borrowed freely; to Kekulé's *Lehrbuch der Organischen Chemie*, 1859; and to Roscoe's translation of Bunsen's *Gasometry*.

GASKELL, MRS ELIZABETH C., an English authoress, was born about the year 1820, and is the wife of a Unitarian clergyman in Manchester. Her maiden name was Stevenson. Her novels, of which *Mary Barton* (1848) and *Ruth* (1853) are perhaps the best examples, are chiefly descriptive of the habits, thoughts, privations, and struggles of the industrial poor, as these are to be found in such a social beehive as the city in which the authoress resides. Some of her characters are drawn with remarkable dramatic power, and many of her descriptive passages are very graphic. Among her other works may be mentioned *The Moorland Cottage* (1850), a Christmas story; *North and South* (1855); *Cranford*; and *Lizzie Leigh*—the last three of which originally appeared in *Household Words*. Mrs G. has edited a very interesting life of Charlotte Brontë (q. v.),

1857. Her last work, *Round the Sofa*, appeared in 1859.

GASOMETER. See GAE.

GASPÉ, the most easterly district of Lower Canada, consisting of the counties of Gaspe and Bonaventure, is chiefly a peninsula projecting into the Gulf of St Lawrence, between the estuary of the same name on the north and the Bay of Chaleur on the south. It stretches in N. lat. between 48° and 49° 20', and in W. long. between 64° 15' and 67° 56', containing 7500 square miles, and about 12,000 inhabitants, the greater number being of French descent. Cod and whale fisheries form the staple business of the country. The district is terminated towards the east by a cape of its own name, and this headland is the northern extremity of a bay also of the same name, which presents a safe and capacious harbour.

GASSENDI, or GASSEND, PIERRE, an eminent French philosopher and mathematician, was born 22d January 1592, at Champtercier, a little village of Provence, in the department of the Lower Alps. His unusual powers of mind shewed themselves at an early age; and in 1616 he became professor of theology at Aix. About this time, he drew upon himself the regards of Pierres, whom Bayle calls the *procureur-general* of literature, and of Joseph Gautier, prior of La Valette, a distinguished mathematician, both of whom liberally gave him the benefit of their instructions and advice. With the first, he studied anatomy; from the second, he derived his taste for astronomical observations. After six years' study, he became disgusted with the scholastic philosophy, and undertook to maintain certain theses against the Aristotelians. His polemic appeared at Grenoble in 1624, and was entitled *Exercitationes paradoxæ adversus Aristoteles*. It was accompanied by an expression of his belief in the church, for whose honour and glory he declared himself 'ready to shed the last drop of his blood.' He drew a distinction for the first time between the church and the scholastic philosophy, denying that the former must stand or fall by the latter. G. now visited Paris, where he made several influential friends. In the same year in which he published his *Exercitationes*, he was appointed *prevôt* of the cathedral at Digne, an office which enabled him to pursue without distraction his astronomical and philosophical studies. In 1628 he travelled in Holland, and got involved in a controversy with Robert Fludd, an English mystic, relative to the Mosiac cosmogony, in which he is admitted to have had greatly the advantage of his incoherent opponent. At the recommendation of the Archbishop of Lyon, a brother of Cardinal Richelieu, G. was appointed professor of mathematics in the College Royal de France, at Paris, where he died, 14th October 1655. As a philosopher, G. maintained, with great learning and ingenuity, most, though not all, of the doctrines of Epicurus, these being most easily brought into harmony with his own scientific acquirements and modes of thought. His philosophy was in such repute, that the savans of that time were divided into Cartesianes and Gassendists. The two chiefs themselves always entertained the highest respect for each other, and were at one time on the friendliest terms. The agreeableness of their intercourse, however, was for a while interrupted by the publication of a work of G.'s, entitled *Dubitationes ad Meditationes Cartesianas*, in which he expressed himself dissatisfied with the tendencies of the new system of philosophy introduced by Descartes, for G. was averse to novelty in the sphere of mental speculation, although he

warmly espoused the side of progress in physical science, and made himself many enemies among his bigoted ecclesiastical brethren for the love he bore it. He ranked Kepler and Galileo among his friends, and was himself the instructor of Molière. His principal work is entitled *De vita, moribus et doctrina Epicuri* (Lyon, 1647), to which the *Syntagma Philosophiæ Epicuriæ* (1649) belongs. It contains a complete view of the system of Epicurus. His *Institutio Astronomica* (1645) is a clear and connected representation of the state of the science in his own day; in his *Tychonis Brahe, Nicolai Copernici, Georgii Peurbachii et Joannis Regiomontani Astronomorum Celeberrimorum Vitæ* (Par. 1654), he not only gives a masterly account of the lives of these men, but likewise a complete history of astronomy down to his own time. G. was pronounced by Bayle the greatest philosopher among scholars, and the greatest scholar among philosophers. His works were collected and published by Montmor and Sorbière (Lyon, 6 vols. 1658).

GASSNER, JOHANN JOSEPH, a man who made a noise as an exorcist in the 18th c., was born 28th August 1727, at Bratz, near Pludenz, in the Tyrol, and became Catholic priest at Klüsterle, in the diocese of Coire. While in that office, the accounts of demoniacs in the New Testament, combined with the writings of celebrated magicians, brought him to the conviction that most diseases are attributable to evil spirits, whose power can be destroyed only by conjuration and prayer. He began to carry out his conviction by practising on some of his parishioners, and succeeded so far as to attract notice at least. The Bishop of Constance called him to his residence, but having come very soon to the conviction that he was a charlatan, advised him to return to his parsonage. G. betook himself, however, to other prelates of the empire, some of whom believed that his cures were miraculous. In 1774, he even received a call from the bishop at Ratisbon, to Ellwangen, where, by the mere word of command, *Cesset* (Give over), he cured persons who pretended to be lame or blind, but especially those afflicted with convulsions and epilepsy, who were all supposed to be possessed by the devil. Although an official person kept a continued record of his cures, in which the most extraordinary things were testified, yet it was found only too soon that G. very often made persons in health play the part of those in sickness, and that his cures of real sufferers were successful only so long as their imagination remained heated by the persuasions of the conjuror. Intelligent men raised their voice against him, and he lost all respect before his death. He died, March 1779, in possession of the wealthy deanery of Benndorf.

GAS-TAR, or COAL-TAR, a thick, black, opaque liquid, which comes over and condenses in the pipes when gas is distilled from coal. It is slightly heavier than water, and has a strong, disagreeable odour. Coal-tar is a mixture of many distinct liquid and solid substances, and the separation of the more useful of these constitutes an important branch of manufacturing chemistry. The tar is first distilled in large malleable iron stills, when *water* and *crude naphtha* first come over; and afterwards, when the temperature rises, a heavy, fetid-smelling oil, called *dead-oil*, which sinks in water. There remains in the still a large residue of *pitch*, which is again distilled in brick ovens, giving off an oil called *coke-oil*, and leaving a large quantity of *pitch-coke*. The crude naphtha is purified by sulphuric acid and quicklime, and re-distilled, when it is nearly as colourless as water. This, then, forms the refined coal-tar naphtha of

commerce. It is largely used for burning in lamps, as a solvent for india-rubber and gutta-percha, to preserve animal substances from moth, and it is also burned to produce a fine carbon for the manufacture of printing-ink. It is from the lighter portion of naphtha, called *benzole*, that the beautiful mauve and magenta colours are manufactured. See BENZOLE and DYE-STUFFS. Benzole is likewise used for removing stains of fat or oil from cloth. The dead-oil or pitch-oil is sometimes used, in its crude state, as a cheap material for affording light in lamps burned in the open air. It contains a considerable quantity of creasote, and forms the best preservative for wood in damp situations. The coke-oil is not of much commercial importance, but it can be burned in lamps, and this, with the dead-oil, when consumed in a confined atmosphere, gives a smoky flame, the soot from which constitutes lampblack. The pitch-coke is valuable as a fuel for melting iron, being free from impurities. Pitch itself is used for making asphalt pavement, and also for roofing-felt.

From the last portion of the distillation of the crude naphtha, and the first of the dead-oil, a beautiful white crystalline solid, called naphthaline, is obtained. It has been long known without being applied to any useful purpose, but is now beginning to be employed for the manufacture of colours, in a similar way to the benzole. The dead-oil also contains considerable quantities of a yellow solid termed paranaphthaline, which is a mere chemical curiosity.

The creasote is extracted from the dead-oil by stirring it with soda, in which the creasote dissolves. When this soda solution is boiled for some hours, and then has an acid added to it, the creasote separates as an oil on the surface of the fluid, and, when distilled, is nearly pure. This treatment requires to be repeated several times to get it quite pure, and to keep its colour. Most of the creasote used by druggists is made from coal-tar. The creasote from wood is a similar but quite distinct body.

Sulphuric acid extracts both from the dead-oil and the crude naphtha several volatile basic oils besides benzole—namely, toluole, xylene, cumole, and cymole, which are almost unknown in the arts, although they may yet come to be of great service. Among them is aniline, but not in sufficient quantity to pay for its extraction. There also occurs a curious body named pyrrol, the vapour of which gives to fir-wood, dipped in muriatic acid, a splendid violet colour. Beautiful blue colours have been made from these basic oils, but only by elaborate and expensive processes.

GASTEROPODA (Gr. belly-footed), or GASTROPODS, a class of molluscs, inferior in organisation to cephalopods, but far superior to almost all other molluscs, and containing a multitude of species, the greater number of which are marine, but some are inhabitants of fresh water, and some are terrestrial. Snails, whelks, periwinkles, limpets, cowries, and the greater number of molluscs with univalve shells belong to this class, and univalve molluscs constitute the greater part of it; but it contains also some molluscs with multivalve shells, as chitons, and some, as slugs, which have either only a rudimentary internal shell, or no shell at all. Some aquatic kinds are destitute of shell in the adult state, but they are protected by a rudimentary shell on first issuing from the egg. No known gastropod has a bivalve shell, unless the *operculum*, which closes the mouth of the shell in many species, be regarded as a second valve.

Gastropods have a head, more or less fully developed, in which is situated the mouth, and

GASTEROPODA.

which generally carries fleshy, retractile tentacula, varying from two to six in number. The tentacula do not encircle the mouth; they seem to be

Fig. showing the soft parts of a Gasteropod (*Dolium Gales*):
a, head, d, d, foot.

special and exquisitely sensitive organs of touch, a sense which the general surface of the body does not seem to possess in a high degree; and in some G., as snails, they carry the eyes at their

senses of taste and smell, and at least some of them that also of hearing, as they not only have a nervous centre analogous to the acoustic division of the brain in vertebrate animals, but a little sac on each side, apparently an organ of this sense. Their nervous system is more complex and concentrated than that of the headless (*acephalous*) molluscs; the principal nervous masses surround the gullet. In the highest G., such as snails, there are only two principal nervous masses, one of which, supplying the nerves connected with sensation, is called the brain.—The blood of G. is often opalescent, with a few colourless corpuscles. The heart is always systemic only, and in almost all consists of one auricle and one ventricle, although a few G. have two auricles, one for each set of gills. Near the commencement of the aorta, there is often a contractile muscular swelling (*bulbus arteriosus*), as in fishes. Respiration takes place generally by gills, which are very variously situated, sometimes externally, sometimes in a special cavity, and exhibit an equally great variety of form and structure; but some G., as snails and slugs, have, instead of gills, a pulmonary sac or cavity, lined with a vascular net-work, these being either inhabitants of the land, or, if of the water, obliged to come occasionally to the surface for the purpose of breathing. A few of the lowest G., doubtfully placed in this class, are destitute of distinct respiratory organs. The digestive apparatus also exhibits much diversity. Some of the G. feed on vegetable, some on animal substances, and some of them on animals which they themselves kill. Thus, whilst snails eat leaves and other soft parts of vegetables, whelks (*Buccinum*) prey on other molluscs, and are provided with a remarkable apparatus at the end of a proboscis into which the mouth is elongated, for filing a hole—as nice as could be made by the drill of a mechanic—through the hardest shell. The mouth of the snail is, in like manner, admirably adapted to the cutting of leaves or similar substances by the action of the lips against a sharp horny plate. Other G. have the mouth furnished with two cutting blades, wrought by powerful muscles. The tongue of some is covered with minute recurved hooks, to prevent the possibility of anything escaping from the mouth; and the stomach of some is a muscular gizzard, provided with cartilaginous or sometimes calcareous projections, or stomachic teeth, to aid in the comminution of the food. The intestine is generally bent back, so that the anus is not far from the head. The liver is large, as are also the salivary glands of many gastropoda. Very great diversities are found in the reproductive system. In some G., the sexes are distinct (*G. DIÖCIA*); others are hermaphrodite (*G. MONÖCIA*); and whilst self-impregnation takes place in some of these, others—as snails—mutually impregnate each other by copulation. In general, the reproductive organs are very largely developed, and are of complex and remarkable structure. The G. are in general oviparous; a few are ovoviviparous. The young of aquatic G. at first swim about actively by means of ciliated fins attached to the head. G. are generally unsymmetrical, one side of the body being developed without the other, some of the principal organs of which—the gills and nerves—are atrophied; and thus the shell with which most of them are covered becomes, in the greater number, spiral, the spire turning towards the unatrophied side, which is generally the right side, although in some (*reversed* or *sinistrotorsal* shells) it is the left. The head and the organ of locomotion are capable of being withdrawn into the last whorl of the shell, and in aquatic species generally, the mouth of the shell can be closed by an operculum (q. v.), exactly fitting

Anatomy of the Whelk (copied from Jones' *Gen. Struc. of An. Kingd.*):

ab, vein of proboscis and its branches; c, c, nervous branches proceeding from the brain to the extremity of the proboscis; d, brain, situated above the œsophagus or gullet; e, nervous branches connecting the brain with the great ganglion or nervous mass beneath the œsophagus; f, tentacula; g, penis; h, liver; i, a large nervous mass beneath the œsophagus; k, l, ganglia; m, one of the two principal trunks of the aorta, supplying the foot and anterior part of the body; n, s, nervous branches connecting ganglia; p, orifice of respiratory cavity; q, branchial vein; rz, heart (r, ventricle, s, auricle); t, one of the two principal trunks of the aorta, winding among the mass of viscera contained in the shell, and distributing its ramifications to them; u, branchial fringes, or gills; w, posterior part of the body, or mass of viscera contained in the shell; x, roof of respiratory cavity thrown back.

tips, but in others the eyes—always small—are situated elsewhere on the head, and a few are destitute of eyes. They are believed to possess the

it, and attached to the foot, but in which many varieties of beautiful structure are exhibited, and which is generally horny, sometimes calcareous. Some shells are simply conical, and there are numerous diversities of form. The shell is secreted by the mantle. See MOLLUSCA, SHELLS, and UNIVALVES. The viscera are contained in a thin sac—part of the mantle—which fills the upper part of the shell. The organ of locomotion, called the foot, is in general a muscular disc, developed from the ventral surface of the body; sometimes, as in limpets, capable of acting as a sucker, and exhibiting other even more remarkable modifications, so that in some it becomes an organ for swimming. G. generally creep by means of this disc adhering to surfaces, and contracting in transverse wrinkles or undulations, which begin from behind. The G. generally secrete a peculiar kind of slime. Some of them also produce other peculiar secretions, of which the Tyrian purple affords an example. G. have a great power of renewing lost parts; tentacles are thus restored, and even the eyes which they bear at their tips, the mouth with all its apparatus, or the head itself.

GASTON DE FOIX. See FOIX.

GASTRALGIA, or GASTRODY'NIA. See CARDIALGIA.

GASTRIC JUICE. See DIGESTION, ORGANS AND PROCESS OF.

GASTRITIS AND GASTRO-ENTERITIS (inflammation of the stomach, &c.). See STOMACH, DISEASES OF, also ENTERITIS.

GASTROCHÆNA, a genus of lamellibranchiate molluscs, having a delicate shell of two equal valves, gaping very much in front; the animal sometimes taking possession of an already existing cavity, which it often lines with a calcareous lining, so as to form a tube, to which the valves of its shell are cemented; sometimes burrowing for itself in sand, madrepores, or calcareous rocks, and lining its hole with a shelly layer. *G. modiolina*, a rare British

supported on the raised foot, the other leg is carried forward. From their close association with the erect position, they are much less developed in other mammals than in the human subject.

GASTRO'DIA, a genus of orchids. *G. sesamoides* is a native of Van Diemen's Land, the roots of which form large coral-like masses, and are sometimes called native potatoes, being edible; but they are watery and insipid.

GASTROSTOMY (Gr. *gaster*, the belly or stomach, and *stoma*, mouth), an operation which has been two or three times performed for the relief of stricture of the gullet, to relieve the patient from the imminent risk of starvation, by introducing food directly into the stomach through an external opening. The well-known case of Alexis St Martin, and numerous experiments on the lower animals, have led to this attempt, not unreasonably, to save life; it has not as yet, however, been successful.

GASTROTOMY (Gr. *gaster* and *tome*, an incision), an incision into the cavity of the Abdomen (q. v.) for the purpose of removing some diseased texture or foreign body. The term has also been applied to Cesarean Section (q. v.).

GATES, HORATIO, a general in the American army in the war of independence, was born in England in 1728. He served under General Braddock, and was severely wounded near Pittsburg in the disastrous campaign of 1755, in which Braddock lost his life. On the breaking out of the revolution, G. espoused the popular cause. His military experience and skill procured his rapid promotion, and in 1776 he was appointed major-general. In August 1777, he took the chief command of the American forces north of Albany, then amounting to about 6000 men, besides some detached bodies of militia. Having been reinforced by the troops under General Lincoln, he defeated Burgoyne (October 7 and 8), and soon after compelled that general to surrender with all his army, consisting of about 5800 men. This success, by far the most important that had been gained by the Americans during the war, procured G. the reputation of a consummate general, and some were even desirous to make him commander-in-chief in the place of Washington.

In 1780, G. was appointed to the command of the southern army, which, though amounting to near 6000 men, was composed chiefly of militia. He was totally defeated near Camden, South Carolina, by Lord Cornwallis (whose force was greatly inferior in numbers to that of G.), with the loss of 800 men killed, and as many more taken prisoners. Congress ordered, soon after, an inquiry into the conduct of G., who was, after a protracted trial, honourably acquitted, and reinstated in his command. He died in 1806. 'His experience,' says Bancroft, 'adapted him for good service in bringing the army into order, but he was shallow in his natural endowments and in his military culture.'

GATESHEAD, a town of England, in the county of Durham, and an ancient borough under the Episcopal palatines of that county, was formerly governed by a bailiff and burgesses, and became a parliamentary and municipal borough under the Reform Act of 1832, and the Municipal Corporations Reform Act of 1835. It is situated on the south bank of the Tyne, directly opposite Newcastle, to which it is joined by two bridges, and with which it is otherwise so closely connected as virtually to form one town with it. The older portions of the town are poorly built, but great extensions have been made westward and southward, in which directions much ground has been laid out in new streets and detached villas. There are numerous dissenting as well as

Gastrochæna Modiolina :

a, one of the tubes broken open, shewing the valves.

mollusc, common in the Mediterranean, perforates shells and limestone, making holes about two inches deep and half an inch in diameter. It sometimes bores right through an oyster into the ground below, and makes for itself a flask-shaped case, with its neck fixed in the oyster-shell. The tubes of some of the tropical species which live in sand are very curious.—To the family *Gastrochænidae* are referred *Aspergillum* and *Clavagella*.

GASTROCNEMIUS MUSCLE, THE, is the muscle forming the greater part of the calf of the leg. It arises by two heads from the two condyles of the thigh-bone, and is inserted by the TENDO ACHILLIS (see the diagram in the article FOOT) at the posterior part of the heel-bone. In man, these muscles possess great power, and are constantly called in use in standing, walking, leaping, &c. In walking, they raise the heel, and, with it, the entire body from the ground; and the body being thus

established churches, a grammar-school founded in 1700, a mechanics' institute, and an hospital (King James's), consisting of the master (who is the rector of Gateshead for the time being) and three brethren who have residences, and twelve others who receive allowances without residence. It has also an excellent dispensary, which was established after a dreadful visitation of cholera in 1831—1832, which carried off 1028 of the population. The numerous coal-mines in the neighbourhood, iron-works and foundries, glass-works, brick, tile, and soap works, ship-building, chemical-works, &c., furnish employment to the inhabitants. There are also extensive manufactures of anchors, machinery, chain-cables, iron-wire and other ropes. At Gateshead Fell are quarries from which the famous grindstones erroneously called, but proverbially known as 'Newcastle grindstones,' are obtained, and exported to all parts of the world. In October 1854, a large portion of the lower part of G., as well as considerable property in Newcastle immediately opposite, was destroyed by an awful explosion and fire, which also caused the death of upwards of 50 persons. G. sends one member to the House of Commons. Pop. in 1851, 25,568; in 1861, 33,589. G. is supposed to have been at one time a Roman station, or outwork to the Roman station at Newcastle, several coins and other relics having been found from time to time. The derivation of the name has been long matter of dispute, but the probability is, that it simply means the head of the *gate* or road with which the Romans connected Newcastle with the southern military divisions and defences.

GATEWAY, the passage or opening in which a gate or large door is hung. This may be either an open way with side pillars or a covered way vaulted or roofed over. The gateway being a most important point in all fortified places, is usually protected by various devices. It is flanked by towers with loopholes, from which assailants may be attacked, and is frequently overhung by a machicolated battlement, from which missiles of every description were poured upon the besiegers. City gates, and gates of large castles, have in all ages been the subjects of great care in construction; and when from some cause, such as the cessation of constant fighting, or a change in the mode of warfare, gateways have lost their importance in a military point of view, they have maintained their position as important architectural works, and where no longer useful, have become ornamental. In very ancient times, we read of the 'gate' as the most prominent part of a city, where proclamations were made, and where the kings administered justice. The Greek and Roman gates were frequently of great magnificence. The propylæa at Athens is a beautiful example, and the triumphal arches of the Romans are the ornamental offspring of their city gates. Most of the towns in this country have lost their walls and city gates; but a few, such as York and Chester, still retain them, and give us an idea of the buildings which formerly existed, but which now remain only in the name of the streets where they once stood. Our castles retain more of their ancient gateways, and from these we may imagine the frowning aspect every town presented during the middle ages. Abbeyes, colleges, and every class of buildings were shut in and defended by similar barriers; many of these still exist in Oxford and Cambridge, and the abbey gates of Canterbury and Bury St Edmund's are well-known specimens of monastic gateways. The feeling of personal freedom, which is so strong in this country, must no doubt have tended greatly to hasten the demolition of these marks of feudalism; but on the continent, where every man has to

present a passport at the gate of the city before entering it, we still find these barriers kept up.

GATH (in Heb. a 'wine-press'), one of the five chief cities of the Philistines, was situated on the frontiers of Judah, and was in consequence a place of much importance in the wars between the Philistines and the Israelites. It formed, in fact, the key of both countries, and was strongly fortified. The famous Goliath, whose gigantic height and swaggering air so frightened the troops of King Saul, and who was slain by the stripling David with pebbles from the brook, was a native of this place. Jerome describes it in his time as a 'very large village.' The site of ancient Gath is probably the little eminence, about 200 feet high, now known as Tell-es-Sâfret, at the foot of what were once called the Mountains of Judah.

GATINEAU, a large river of North America in Canada East, has its origin in a connected chain of large lakes lying immediately north of the 48th parallel of latitude. It flows in an almost undeviating course south-south-west, and falls into the Ottawa, in lat. 45° 24' N., long. 75° 43' W., 12 miles below the town of Aylmer. The length of this river has not been definitely ascertained, but it is said that canoes have navigated it for upwards of 300 miles. Steamers have ascended it for four miles.

GATSKHINA, a town of Russia, in the government of Petersburg, and about 30 miles south-south-west of the city of that name, is charmingly situated on a small lake formed by the Ishora. It is regularly built, has an educational institution for foundlings, a horticultural school, and some manufactures of porcelain; but is especially worthy of mention for its royal palace, a structure at once simple in its style and imposing in its effect. This palace, which contains 600 apartments, and is surrounded by one of the finest pleasure-gardens in Europe, was the favourite seat of the Emperor Paul I., who bestowed municipal rights upon the town of G. in 1797. Pop. variously stated at from 4500 to 7000.

GAU (of doubtful origin, possibly allied to Gr. *ga*, land), a German word meaning, in a general way, country (as opposed to the town), district; but applied specially to a political division of ancient Germany, having relation to the arrangements for war and the administration of justice. A *gau* embraced several communities or villages, and had one or more *grafs* (q. v.) and judges over it. As the *grafsdoms* became more and more hereditary, the *gau*, as a political division, fell into disuse (about the 12th c.), and only in the names of some places do the traces of it remain. The Abbot Bessel gave a complete account of the geography of the German *gaus* in his *Chronicon Gotthwicense*; and Spruner's *Historical Atlas* contains a map of them. The nature of the *gau* system is fully discussed in the works of Eichhorn, Waitz, and Bethmann-Hollweg. See **HUNDRED**.

GAUGE. See **GAGE**.

GAUGER, an officer of Excise, whose duty it is to gauge or measure casks containing excisable liquors or other commodities. Such persons are precluded from dealing in excisable commodities under the penalty of forfeiture of office, and incapacity to fill any other in connection with the excise; and the crime of accepting a bribe is punishable with the penalty of £500, and incapacity for any government office.

GAUL. See **FRANCE**.

GAULT, a member of the Cretaceous Formation (q. v.), separating the Lower from the Upper Green

sand. It consists of an upper part, hard and sandy, and containing green particles scattered through it; and of a lower portion, a stiff dark gray, blue, or brown clay, smooth and uniform in texture, and very plastic, which is manufactured into tiles, bricks, and even common pottery. Concretions of iron pyrites and other nodules are not uncommon in the Gault. The contained fossils are for the most part beautifully preserved, having been protected from decay by being buried in the tenacious and compact mud which forms the Gault beds. The most abundant remains are those of cephalopodous mollusca, as ammonites, scaphites, and turrilites.

The Gault occurs at Folkstone, and stretches west through Kent and Surrey into Hampshire, and then, turning eastwards through Sussex, it is seen on the coast near Beechy Head. It also stretches in a narrow line from Dorsetshire, in a north-easterly direction, through the centre of England, till it reaches the coast at Hinstanton, in Norfolk. Its maximum thickness is 150 feet. In Surrey, the Gault supplies considerable quantities of phosphatic nodules, largely used by agriculturists for fertilizing soils.

The Blackdown beds in Dorsetshire are probably contemporaneous with the Gault, the one having been deposited near the shore, while the fine mud of the Gault was carried out to sea. The Blackdown beds, however, contain Greensand fossils mixed with those of the Gault, so that the exact age of the deposit is still doubtful.

GAULTHERIA, a genus of small procumbent or nearly procumbent evergreen shrubs, of the natural order *Ericaceæ*, the fruit of which is a 5-valved capsule, covered with the enlarged and fleshy tube of the calyx. They are natives of temperate regions. *G. procumbens* is a common

SHALLOON (*G. shallon*) is a comparatively large species, two or three feet high, with purple berries, which are agreeable to the palate, and form a considerable part of the food of Indians in the north-west of America, of which the plant is a native. It grows well under the shade of woods, and has of late been planted in many places in Britain, to afford food for pheasants and other kinds of game.—*G. hispida* is a native of Van Diemen's Land, bearing snow-white berries, and known by the name of WAX-CLUSTER. The berries are eaten. — Other species, some of which are fragrant, some produce edible berries, and all are beautiful little shrubs, are found in the Himalaya Mountains, the mountains of South America, Australia, &c. The Australian *G. antipoda* is said to be a finer fruit than *G. hispida*.

GAUR, or GOUR (*Bos Gaurus*), a species of ox, inhabiting some of the mountain jungles of India. It is of very large size, although apparently inferior to the Arnee (q. v.). It bears a considerable resemblance to the Gayal (q. v.), but differs from it in the form of its head, and in the total want of a dewlap, in which it more nearly agrees with the Banteng of the Eastern Archipelago, although distinguished from it by important anatomical peculiarities. See BANTENG. The back is strongly arched, having a

Gaur (*Bos Gaurus*).—From Routledge's *Natural History*.

remarkable ridge of no great thickness, which rises above its general line, owing to an unusual elongation of the spinous processes of the vertebrae. The hair is remarkably short and sleek. The G. is formidable even to the tiger, and safe from his attacks. It is usually found in herds of from ten to twenty. It is extremely abundant in the high insulated tableland of Myn Pat, in South Bahar, and in the adjoining steep and narrow valleys. It is supposed to be incapable of domestication; frequent attempts for this purpose are said to have been made in Nepal.

GAURITZ, a river of the south coast of the Cape Colony, in South Africa, forms the eastern boundary of the district of Zwellendam, entering the sea a little to the west of Mossel Bay. Like nearly all the streams of this region, it is rapid, and almost useless for the purposes of navigation.

GAUSS, KARL FRIEDRICH, one of the most illustrious mathematicians of modern times, was born at Brunswick on the 30th of April 1777. In 1795, he went to the university of Göttingen, where, at this early age, he made a number of important discoveries, one of which may be mentioned, as it had occupied the attention of geometers from the time of Euclid, viz., the division of the circle into 17 equal parts

Procumbent Gaultheria (*Gaultheria procumbens*):
a, fruit; b, flower.

plant in North America as far south as Virginia, and bears the names of PARTRIDGE BERRY, DEER BERRY, WINTER GREEN, and MOUNTAIN TEA. It is about four or five inches in height, with small whitish flowers and red 'berries,' which are eatable, but not safe in any considerable quantity, because of the pungent volatile oil which they contain. Brandy in which they have been steeped is used as a tonic. The whole plant has an agreeable aromatic odour and taste, owing to the presence of volatile oil, which, when extracted, is used in medicine as a stimulant, also by druggists for flavouring sirups, and to a considerable extent in perfumery, under the name of Oil of Winter Green. The leaves are used both as an astringent and as a stimulant; and an infusion of them is used as tea in America, for which purpose those of another species are also employed in Nepal.—The

He soon afterwards returned to Brunswick, and there, in 1801, published his *Disquisitiones Mathematicæ*, a work treating of indeterminate analysis or transcendental arithmetic, which contains, besides other important theorems, a new demonstration of that of Fermat concerning triangular numbers. While G. was at work on these speculations, he was in great measure ignorant of what had been done in the same subject by previous mathematicians, which accounts for the presence in his work of a number of old theorems. But the discovery of the planet Ceres on the first day of the 19th c. guided the energies of G. into a new field of research. He was one of the first to calculate the elements of its orbit, according to methods of his own invention, and his assiduous application, and the accuracy of his results, excited general admiration. On the discovery of Pallas by Olbers in 1802, G. set himself to calculate its orbit; and his results, valuable at the time, are even now models of ingenuity and research. For these labours, he received, in 1810, from the French Institute, the medal founded by Lalande. In 1807, he was appointed director of the Observatory at Göttingen, an office peculiarly suited to his tastes, and about this time commenced to prepare for publication his celebrated work, *Theoria Motus Corporum Cælestium in Sectionibus Conicis Ambientium*, which appeared in 1809. In this work, G. has developed a method of calculating, in the most simple, and at the same time most exact manner, the orbits of the bodies in the solar system. It is also to him that the credit is chiefly due of discovering the great comet of 1811, the elements of whose orbit he calculated with the most surprising accuracy.

In 1821, G. was charged by the Hanoverian government with the triangulation of the kingdom of Hanover, and the measurement of an arc of the meridian. In executing this work, G. found that the appliances then in use did not allow of the vertices of the triangles being seen from a considerable distance with sufficient distinctness, and to remedy this defect, he invented the Heliotrope (q. v.). About 1831, Wilhelm Edward Weber arrived at Göttingen, and communicated to G. a part of his own enthusiasm for magnetic researches. It would take up too much space to give a full account of the many discoveries he made in this new branch of study; suffice it to say, that he has invented a 'magnetometer' which measures the 'magnetic intensity' with great accuracy, and that he has probably contributed more to the advancement of this branch of science than any one before him. G. was pronounced by La Place to be the greatest mathematician of Europe. He died at Göttingen on the 23d of February 1855. Among his most celebrated works, besides the two above mentioned, are the *Disquisitio de Elementis Ellipticis Palladis ex Oppositionibus Annorum 1803—1809* (1810); *Theoria Combinationis Observationum Erroribus Minimis Obnoxia* (Göttingen, 1823), containing a full explanation of his peculiar method above mentioned; *Intensitas vis Magneticæ Terrestris ad Mensuram Absolutam Revocata* (1832), &c.

GAUZE, a light transparent silken fabric, supposed to have derived its name from having first been manufactured in Gaza, a city of Palestine. France and Switzerland produce considerable quantities of gauze. The chief seats of the manufacture in Great Britain are Paisley and Glasgow, and the surrounding districts. The openness of texture is obtained by crossing the warp threads between each thread of the weft, so that the weft passes through a succession of loops in the warp, and the threads are thus kept apart, without the liability to sliding from their places, which would take place if simple

weaving were left so loose and open. Inferior qualities of gauze are made of a mixture of silk and cotton.

GAVA'ZZI, ALESSANDRO, a popular Italian preacher and reformer, distinguished by his patriotic zeal in promoting the civil and religious progress of his country, was born at Bologna in 1809. At the early age of 16, he became a monk of the Barnabite order, and subsequently was appointed professor of rhetoric at Naples, where he speedily acquired great reputation as an orator. By his uncompromising advocacy of church and state reformation, he earned at once the enthusiastic admiration of the progressive party among his countrymen, and the bitter enmity of the priestly and ruling powers.

On the accession of Pius IX. to the papal chair, G. was one of the foremost supporters of the liberal policy that inaugurated that pontiff's reign; and having repaired to Rome, he devoted himself to the diffusion of political enlightenment and patriotic aspirations among the masses of the Roman population. The pope sanctioned his political labours, and appointed him almoner of a body of 16,000 Roman troops, who volunteered for the campaign of Lombardy in 1848, and quitted Rome to proceed to Vicenza. To G.'s fervid and patriotic oratory may be attributed, in no slight degree, the universal spirit of self-sacrifice evoked throughout Italy during this period of her history. He was called the *Pietro Eremita*, or Peter the Hermit of the national crusade. The Roman legion having been recalled by the pope, G. continued in Florence, Genoa, and Bologna, to agitate in favour of the national movement. On the establishment of the republic at Rome, he was appointed almoner-in-chief to the national army. Under his superintendence, efficient military hospitals were organised and attended by a band of Roman ladies, who volunteered their services and co-operation in the care of the wounded. Rome having fallen, G. escaped to England, where he delivered numerous addresses and lectures, illustrative of the political and religious aims of his country. Recent events have enabled him to return again to Italy, and he is once more the foremost of his fellow-countrymen in the advocacy of the civil and religious progress of his native land. He has for some time completely broken with the papacy, not only in its temporal, but in its religious aspect; yet he is not, and does not wish to be considered as exactly a Protestant. He proclaims the necessity of a return to primitive and apostolic Christianity, but is not disposed to accept for Italy any ready-made theological system from abroad. His leading doctrine, however, 'Justification by Faith,' is apparently the same, at least in form, as that held by the reformers of the 16th century.

GAVELKIND. Lappenberg, who, though a foreigner, when endorsed by his translator Thorpe, may be considered as the very highest authority on the subject of English social antiquities, thus speaks of the custom of gavelkind: 'A fact worthy of notice is the existence down to recent times of the old British law of succession in Wales, Kent, and some parts of Northumberland, called gavelkind. As far as we are enabled to understand it, in its mixture with Anglo-Saxon law, all the sons of the father inherited, but the youngest possessed the homestead; the eldest, or the next following capable of bearing arms, had the heriot—that is, the arms offensive and defensive of his father, and his horse. Even the son of an outlaw could not be deprived of the entire succession, but of the half only' (vol. i. p. 39). Though a Celtic origin is here,

as by Blackstone (Stephen, iv. p. 548), probably with reason, ascribed to this tenure, it seems to be the general opinion of legal antiquaries (Selden, *Analect.* l. 2, c. 7; Stephen, vol. i. 213) that it prevailed over the whole kingdom in Anglo-Saxon times, and that in Kent and elsewhere it was among the 'liberties' which the people were permitted to retain at the Conquest. Most of the many derivations which have been suggested for the word are, moreover, Teutonic—*gaf eal cyn*, equivalent to Lord Coke's *gave all kinde*, or the custom which gives to all children alike, being the most probable. In Wales, gavelkind obtained universally till the time of Henry VIII. (34 and 35 Henry VIII. c. 26), and in some parts of England it is not yet abolished. In Kent, all lands that have not been disgavelled by act of parliament, are held to be gavelkind—a fact which ought to be borne in mind in all transactions with Kentish property. In addition to the characteristics of this tenure already noticed, Blackstone mentions the following: '1. The tenant is of age sufficient to alien his estate by feoffment at the age of 16. 2. The estate does not escheat in case of an attainder for felony; their maxim being, "the father to the bough, the son to the plough." 3. In most places, the tenant had a power of devising lands by will before the statute authorising the devise of lands generally was made.'

GAVIAL (*Gavialis*), a genus of reptiles of the Crocodile (q. v.) family, conspicuously differing from true crocodiles and from alligators in the great length and slenderness of the muzzle. Another peculiar character is a large cartilaginous swelling at the extremity of the muzzle in the males, around the orifice of the nostrils. The teeth are very numerous, about 120; they are more equal in size than those of the other animals of this family, although some of the first are rather larger than the rest, the longest of the lower jaw being received into notches in the upper, as in the true crocodiles. The head is very broad, the narrow muzzle begins abruptly, and in it the branches of the bone of the lower jaw are united and prolonged as one. There are two great perforations in the bones of the skull behind the eyes, externally marked by depressions.

Gavial (Gavialis Gangeticus).

The plates which cover the back and the nape of the neck are united. The crest of the tail is much elevated; the feet are webbed to the extremity of the toes, the whole habits as aquatic as those of the crocodile of the Nile. The only perfectly ascertained species, *G. Gangeticus*, inhabits the Ganges. It attains a greater size than any other

of the recent *Crocodylidae*, frequently attaining the length of 25 feet; but owing to the slenderness of its muzzle, it is esteemed less dangerous than a true crocodile of smaller size. The form of the muzzle seems particularly to adapt it for preying on fish. The cartilaginous swelling at the extremity of the muzzle seems to have given rise to *Aelian's* statement, that the crocodile of the Ganges had a horn at the tip of its snout. Fossil gavials, different from the existing species, have been found in Eocene deposits, as at Bracklesham, in England.

GAVINANA, or **CAVINANA**, a village of 622 inhabitants, picturesquely situated amid the Tuscan Apennines, in the valley of the river Lima, owes its interest to the memorable battle fought around its walls in 1530, between the republican forces of Florence, led by their great captain, Ferruccio, and the Imperialists headed by Philibert, Prince of Orange. The Florentines were defeated with the loss of their commander; and the death of Ferruccio, whose name in Tuscany has become synonymous with chivalry and patriotism, gave the final blow to the liberties of the republic.

GAVOTTE, a piece of music of a lively character, peculiarly suitable for dancing, but more adapted for the stage than for private performance. It consists of two repetitions of eight bars each, beginning with an up-beat, and is in alla-breve time. The fundamental rhythm of the gavotte is therefore

by which the second bar has a remarkable caesura. Formerly, the gavotte was often introduced into sonatas and other pieces, where its form was not so strictly adhered to; still the eight-bar repetition was always considered necessary.

GAY, JOHN, was born at Barnstaple, in Devonshire, in 1688. Although of an ancient family, his father was in reduced circumstances, and G. was apprenticed to a London silk-merchant; but disliking his occupation, he was finally released from it by his master. In 1711, he published a descriptive poem, dedicated to Pope. The year after, he was appointed secretary to the Duchess of Monmouth. His next work was *The Shepherd's Week*, in *Six Pastorals*, which gained considerable applause. About the same time he produced *Trivia* and *The Fan*, full of descriptions of low city-life, a good deal in Swift's style—indeed, he was assisted by Swift in the former work. In 1713, appeared his comedy, *The Wife of Bath*, which did not succeed. Next year, he relinquished his situation in the family of the Duchess of Monmouth, and accompanied Lord Clarendon, then envoy-extraordinary to Hanover, as his secretary. Within two months, he was again in London, where, at the instigation of Pope, he wrote a poem on the Royal Family, and shortly afterwards produced his play, *What d'ye Call It?* Encouraged by its success, he brought out another play entitled *Three Hours after Marriage*, which failed signally. In 1720, he published his poems by subscription, and is said to have realised £1000 thereby. He at the same time received a present of South Sea stock, and was considered a rich man, when all his sudden fortune was lost in the collapse of that famous bubble. In 1724, he produced his play of *The Captives*, and wrote a volume of *Fables* in 1726. When Swift came to live with Pope at Twickenham in 1726, he talked to G. of a Newgate pastoral, and *The Beggars' Opera* was the result. The success of this piece was immense; it had a run of sixty-three nights, and took captive town and country. G. afterwards wrote a sequel, entitled *Polly*, but

owing to some misunderstanding with the lord chamberlain, its representation was prohibited. On its publication, it brought the author £1200. About this time, he went to live with the Duke of Queensberry, and remained with him during the rest of his life. He was seized with an inflammatory fever, and died after an illness of three days. His death took place on the 4th December 1732, and he was buried in Westminster Abbey.

Although more than a century has elapsed, and the satire and the allusions are obsolete, *The Beggar's Opera* is still occasionally represented. It exists, however, mainly in virtue of its songs and music. G. had a happy lyrical vein, and could turn a stanza on the beauty of woman, and the fascinations of the wine-cup, and the fleeting of youth, with considerable grace. His *Fables*, and his serious and comic poems, are only now to be found in libraries. The wit and the sentiment are alike dust. Of all he has done, his ballad of *Black-eyed Susan* possesses the strongest vitality, and thrills now and then our theatres and concert-rooms.

GAY'AH, the capital of the district of Bahar, in the sub-presidency of Bengal, stands on the Phalga, an affluent of the Ganges, in lat. 24° 48' N., and long. 85° 4' E. It contains about 45,000 inhabitants; but as it is a place of great sanctity, it is annually visited by at least 100,000 pilgrims. It consists of two towns—the older being reserved for the Brahmins and their immediate dependents, and the newer being occupied by the population at large—and on an intermediate area stand the public establishments. The people rely chiefly on the expenditure of the superstitious visitors, some of whom have been known to leave behind them £5000 each.

GAYAL (*Bos Gavvus*), a species of ox, found wild in the mountains of Aracan, Chittagong, Tipura, and Sylhet, and which has long been domesticated in these countries and in the eastern parts of Bengal. It is about equal in size to the Indian buffalo; and, like the buffalo, it carries the head with the muzzle projecting forward. The head is very broad and flat at the upper part, suddenly contracted towards the nose; with short

to secure which the animals are occasionally supplied with a little salt, which has the greatest attractions for them. Their milk is extremely rich, but not abundant; the Kookies, however, do not use the milk, but rear them entirely for their flesh and skins.

GAY-LUSSAC, LOUIS JOSEPH, one of the most distinguished chemists and physicists of recent times, was born on the 6th of December 1778, at St Léonard (Haute-Vienne). In 1795, he was sent to Paris to prepare for the examinations requisite for admittance into the Polytechnic School; and his admission to that institution took place on the 27th December 1797. After three years' study, he was promoted to the department *Des Ponts et Chaussées*. Berthollet, who was then Professor of Chemistry in the Polytechnic School, having recognised his zeal and talents for original research, selected him as his assistant at Arcueil, where the government chemical works were situated. The study of Dalton's *Experimental Essays*, published in 1801, directed the attention of the young chemist to the department of chemical physics. In that year he published his first Memoir, which treated of 'the dilatation of gases and vapours,' and which was speedily followed by others on 'the improvement of thermometers and barometers;' on 'the tension of vapours, their mixture with gases, and the determination of their density, &c.;' and on 'capillary action.' In consequence of the reputation which he acquired from these researches, he was commissioned, in association with Biot, by the Institute of France, to make a balloon ascent, with the view of ascertaining whether the magnetic force existed at considerable heights above the surface of the earth, or only on the surface, as had been asserted by some physicists. A notice of this ascent, and of another ascent which he made alone, is given in the article BALLOON. Alexander von Humboldt investigated with him the properties of air brought down from a height of more than 23,000 feet, and their joint Memoir to the Academy of Sciences (read on the 1st of October 1804) contained the first announcement of the fact, that oxygen and hydrogen unite to form water in the simple proportion of 100 parts by bulk (volumes) of the former to 200 parts of the latter. The simplicity of the ratio in which these gases stood to each other in their combining proportions, induced him to study the combining volumes of other gases, and thus led him to the important discovery of the *law of volumes*, which was announced in 1808, and is one of the most general and important laws in the whole domain of chemistry. Davy's discoveries of potassium and sodium, by the decomposing action of the voltaic pile, having excited much attention in France, Napoleon directed G. and Thenard to pursue this class of researches. The results of these investigations appeared in their *Recherches Physico-chimiques*, in two volumes, published in 1811. Amongst the most important of the discoveries announced in these volumes, are a new chemical process which yields potassium and sodium much more abundantly than the voltaic pile, the determination of the composition of boracic acid both analytically and synthetically, and new and improved methods of analysing organic compounds. (Boron was, however, simultaneously discovered in England by Davy.) Although the discovery of iodine (in 1811) is due to Courtois, it was G. who (in 1813) first described its distinctive properties, gave it the name which it now bears, and proved that it is an elementary body; he was also the first to form synthetically the compounds of iodine with hydrogen and oxygen, known as hydriodic and iodic acids. In 1815, he announced the discovery

Gayal Cow (*Bos Gavvus*).

horns, a little curved, projecting nearly in the plane of the forehead, and a very wide space between them at the base. There is no proper hump, but a sharp ridge on the shoulders and fore-part of the back. The prevailing colour is brown, generally dark. The Kookies keep herds of gayals, which they permit to roam at large during the day in the forests, but which return home at night of their own accord;

of cyanogen, which presented the first known example of a compound body (C N) exhibiting many properties which were previously believed to pertain specially to simple or elementary bodies. His Memoir on this compound, in the 95th volume of the *Annales de Chimie*, is a model of what a complete and exhaustive chemical investigation should be. Our space will not allow of more than a passing allusion to his subsequent investigations regarding the fabrication of hydrated sulphuric acid, his essays on the bleaching chlorides, on the alcohols, and on the alkalis employed in commerce. In 1805, he was chosen a member of the Committee of Arts and Manufactures, established by the Minister of Commerce. In 1818, he was appointed to superintend the government manufactory of gunpowder and saltpetre; and in 1829, he received the lucrative office of chief assayer to the mint, where he introduced several important chemical changes. In 1831, he became a member of the Chamber of Deputies; and in 1839, he was made a peer of France. He never, however, took an active part in politics, and was diligently engaged in scientific research until his last illness. For many years, he was the editor, in association with Arago, of the *Annales de Chimie et de Physique*. He died at Paris, 9th May 1850, from atrophy of the heart.

GAZA, THEODORUS, a successor of Emanuel Chrysoloras as teacher of the Greek language and literature in the West. When his native city, Thessalonica, fell into the hands of the Turks, in 1430, he fled to Italy, where he studied the Latin language, under Victorinus of Feltra, at Mantua; after 1441, he was appointed rector of the newly established gymnasium, or high school, of Ferrara, and professor of Greek. He was invited by Pope Nicholas V., along with other learned Greeks, to Rome, and was employed in making Latin versions of Greek authors. After the death of Nicholas, King Alfonso invited him to Naples in 1456; but two years after, the death of this monarch also necessitated his return to Rome, where he found a patron in Cardinal Bessarion, who obtained for him a small benefice in the south of Italy, either in Apulia or Calabria. Here he died in 1478, at an advanced age.

G. has been warmly praised by subsequent scholars, such as Politian, Erasmus, Scaliger, and Melancthon. His principal writings are his *Introductivæ Grammaticæ*, libri iv. (a work on the elements of Greek grammar, first published by Aldus Manutius at Venice, 1495 A.D., and long held in high repute), a number of epistles to different persons on different literary subjects, and a variety of important translations into Latin of portions of Aristotle, Theophrastus, St Chrysostom, Hippocrates, and other Greek writers.

GAZA (Heb. signifies 'strong'), (now called GAZER), a town in the south-west of Palestine, is situated about three miles from the sea, on the borders of the desert which separates Palestine from Egypt. It originally belonged to the Philistines, and was a place of importance at the period of the conquest of Canaan by the Israelites. It is frequently mentioned in the history of Samson; and after many vicissitudes in the wars between the Israelites and the Philistines, it was allotted to the tribe of Judah, in whose possession it finally remained. In the year 333 B.C., G. was taken by Alexander the Great; and from that period down to 1799, when it was taken by the French under Kleber, it has been the scene of many battles and sieges. Constantine the Great, who rebuilt the town, made it the seat of a bishop. The modern G. has the appearance of being a collection of mere

villages. It has no gates, no fortifications or defences of any kind. The only building of interest is the great mosque, with its tall octagonal minaret and peaked roof. G. has manufactures of soap and cotton stuffs; and, owing to its situation near the Mediterranean and on the caravan route to Egypt, it has a good trade both by sea and land. Pop. upwards of 15,000, from 200 to 300 of whom are Christians, and the rest Mohammedans.

GAZE, in Heraldry. When a beast of the chase, as a hart or stag, is represented as *affrontée*, or full-faced, it is said to be at gaze.

GAZELLE (*Antilope Dorcas* or *Gazella Dorcas*), a species of antelope, about the size of a roebuck, but of lighter and more graceful form, with longer and more slender limbs, in these respects exhibiting the typical characters of the antelopes in their highest perfection. It is of a light tawny colour, the under parts white; a broad brown band along each flank; the hair short and smooth. The face is reddish fawn-colour, with white and dark stripes. The horns of the old males are nine or ten inches long, bending outward and then inward, like the sides of a lyre, also backward at the base, and forward at the tips, tapering to a point, surrounded by thirteen or fourteen permanent rings, the rings near the base being closest together and most perfect. The horns of the female are smaller and obscurely ringed. The ears are long, narrow, and pointed; the eyes very large, soft, and black; there is a tuft of hair on each knee; the tail is short, with black hairs on its upper surface only, and at its tip. The G. is a native of the north of Africa, and of Syria, Arabia, and Persia. Great herds of gazelles frequent the northern borders of the Sahara; and notwithstanding their great powers of flight, and the resistance which they are capable of making when compelled to stand at bay—the herd closing together with the females and young in the centre, and the males presenting their horns all around—lions and panthers destroy them in great numbers. The speed of the G. is such that it cannot be successfully hunted by any kind of dog, but in some parts of the East it is taken by the assistance of falcons, of a small species, which fasten on its head, and by the flapping of their wings blind and confuse it, so that it soon falls a prey to the hunter. It is also captured in enclosures made near its drinking-places. Although naturally very wild and timid, it is easily domesticated, and, when taken young, becomes extremely familiar. Tame gazelles are very common in the Asiatic countries of which the species is a native; and the poetry of these countries abounds in allusions both to the beauty and the gentleness of the gazelle. It has been supposed that the gazelles of Asia may be of different species from the African, but there is reason to think that they are the same. The Ariel G. (*A. Arabica*) perhaps differs rather as a variety than as a species, and is even more symmetrical and graceful than the common kind. There are several species very nearly allied to the G., among which is *Antilope* (or *Gazella*) *Soemmerringii*, a native of Abyssinia, with the curvatures of the horns very marked and sudden.—Some confusion has arisen among naturalists as to the application of the name G., originally Arabic; and it has not only been given to the *leucoryx* of the ancients, a very different species, but even to the *gemeboc* of South Africa. The true G. was known to the ancients, and is accurately described by *Ælian* under the name *dorcas*, which was also given to the roe.

GAZETTE. A gazette was a Venetian coin worth somewhat less than a farthing; and the name was hence applied to a sort of gossiping sheet, or

primitive newspaper, that was sold for that sum at Venice. See **NEWSPAPER**. In its English acceptation, it means the official newspaper, in which proclamations, notices of appointments, and the like, are published by the government. The *Gazette* is said to have been published for the first time at Oxford in 1665. On the removal of the court to London, the title was changed to the *London Gazette*. It is now published on Tuesdays and Fridays. Proclamations printed in the *Gazette* are probative, without production. But the rule is different as to presentations or grants to private persons. Publication of a dissolution of partnership in the *Gazette* is not a sufficient notice to persons who were formerly in the habit of dealing with the company. Even as regards parties dealing for the first time, the tendency in England is to doubt the sufficiency of such notice in all cases; whereas, in Scotland, the opposite tendency prevails, and it is held that persons contracting with a company for the first time are bound to inquire into its existing condition, and consequently that notice even in a provincial newspaper may suffice. In practice, all reasonable means ought to be resorted to. Under the Bankrupt Act and other statutes, certain notices are directed to be given in the *Gazette*.

GAZETTEER. See **DICTIONARY** and **ENCYCLOPEDIA**.

GAZOGÈNE. See **AERATED WATER**.

GAZONS, in Fortification, are sods laid over newly made earthworks, to consolidate them, and prevent the soil from rolling down.

GEARING, a term applied to the parts of machinery by which motion in one part of a machine is communicated to another; gearing consists in general of toothed-wheels, friction-wheels, endless bands, screws, &c., or of a combination of these. When the communication between the two parts of the machine is interrupted, the machine is said to be *out of gear*; and when the communication is restored, it is said to be *in gear*. In the case of a thrashing-mill, e. g., driven by a steam-engine, the gearing usually consists of an endless band which communicates motion from the axle of the fly-wheel to that of the drum. If the band were slipped off from one wheel, or slackened so that motion could not be communicated by means of it, then the machine would be *out of gear*. Gearing which can be put in and out of gear is called *movable gearing*; that which cannot, as, for instance, the wheel-work of a watch, is called *fixed gearing*. Gearing which consists of wheel-work or endless Screws (q. v.) is put out of gear either by means of one of the wheels sliding along its axis, or being moved out of its place horizontally or vertically by means of a lever. *Straight gearing* is used when the planes of motion are parallel to each other; *bevelled gearing*, when the direction of the plane of motion is changed. See **WHEELS**, **TOOTHED**. Gearing has also for its object the increasing or diminishing of the original velocity, and in reference to this, is distinguished by the term 'multiplying' or 'retarding.' See **WHEELS**, **TOOTHED**.

GEBA RIVER. See **SENEGAMBIA**.

GEBANG PALM (*Corypha Gebanga*), a fan-leaved palm, native of the East Indies, and one of the most useful palms of that part of the world. Its stem yields a kind of sago; its root is medicinal, being both emollient and slightly astringent, so as to be particularly adapted to many cases of diarrhoea; its leaves are used for thatch, for making broad-brimmed hats, and for various economical purposes; its young leaves are plaited into baskets

and bags, in the manufacture of which many of the people of Java find much employment; the fibres of its leaf-stalks are made into ropes, baskets, nets, cloth, &c.—To the genus *Corypha* belongs also the **TALIPAT PALM** (q. v.).—The fruit of *C. Pumas*, a Mexican species, is eatable, and has a sweet taste.

GEBIR, **ABU-MUSHAH-JAAFER AL SOFI**, the founder of the Arabian school of chemistry, flourished towards the end of the 8th, or the commencement of the 9th century. The place of his birth is uncertain. According to the majority of authorities, he was born at Tûs, in Khorassan, but Abulfeda supports the claims of Harran in Mesopotamia. He was greatly esteemed in the East, and subsequently in Europe, where the chemists, down to the time of Van Helmont, did nothing more than repeat his experiments. Cardan reckons G. one of the twelve subtlest geniuses of the world, while Roger Bacon bestows upon him the epithet 'magister magistrorum.' He wrote an immense number of treatises on alchemy, of which a considerable number are extant in the form of Latin versions. The library of Leyden contains many manuscripts of G.'s works which have never been published. In the Imperial Library at Paris there are manuscripts of his two celebrated works, the *Summa Collectionis Completenti Secretorum Naturæ*, and the *Summa Perfectionis*—also of a work on Astronomy, and a treatise on Spherical Triangles. The principle laid down by G. at the commencement of his works is, that art cannot imitate nature in all things, but that it can and ought to imitate her as far as its limits allow. An edition of his works in Latin was published at Dantzic in 1682, and another in English by Russell (London, 1678). For information respecting G.'s opinions with regard to alchemy, see **ALCHEMY**.

GECKO (*Gecko*), a genus of Saurian reptiles, constituting a family, *Gekkotidae*, which some recent naturalists have divided into many genera. The geckos are of small size, and generally of repulsive aspect; the colours of most of them are dull, and

Gecko (*Platydictylus homalocephalus*):

1. Foot of *P. Cepedianus*; 2. Foot of *P. Hameisquitti*; 3. Foot of *P. Lachlanus*; 4. Claw of *Gymnodactylus pulchellus*; 5. Foot of *Thecodactylus thecomyz*; 6. Foot of *Gymnodactylus scaber*.

the small granular scales with which they are covered are in general mingled with tubercles. The legs are short, the gait usually slow, measured, and stealthy, although geckos can also run very nimbly when danger presses, and often disappear very suddenly when they seem almost to be struck or

caught. The feet are remarkable, being adapted for adhering to smooth surfaces, so that geckos readily climb the smoothest trees or walls, or creep inverted on ceilings, or hang on the lower side of the large leaves in which tropical vegetation abounds. The body and tail are never crested, but are sometimes furnished with lateral membranes, variously festooned or fringed. The lateral membrane is sometimes even so large as to be of use to arboreal species in enabling them to take long leaps from branch to branch. The geckos feed chiefly on insects. They are more or less nocturnal in their habits. They are natives of warm climates, and are very widely distributed over the world. Two species are found in the south of Europe, both of which frequently enter houses, as do the geckos of Egypt, India, and other warm countries. The name G. is derived from a peculiar cry often uttered by some of the species, and which in some of them resembles syllables distinctly pronounced, whilst others are described as enlivening the night in tropical forests by a harsh cackle. The geckos have, in almost all parts of the world where they are found, a bad reputation as venomous, and as imparting injurious qualities to food which they touch, but there is no good evidence in support of any such opinion, in accordance with which, however, an Egyptian G. is even known as *the father of leprosy*.

GEDDES, ALEXANDER, LL.D., a biblical critic, translator, and miscellaneous writer, was born at Arradowl, in the parish of Ruthven, Banffshire, in 1737. His parents were Roman Catholics, and young G. was educated for a priest, first at Sculan, a monastic seminary in the Highlands, and subsequently at the Scots College, Paris, where he acquired a knowledge of Hebrew, Greek, Italian, French, Spanish, German, and Low Dutch. In 1764, he returned to Scotland, and, having taken orders, he was appointed officiating priest to the Roman Catholics of Angus, but after a short time went to reside with the Earl of Traquair. In 1769, he undertook the charge of a Roman Catholic congregation at Auchinhalrig, in Banffshire, where he remained for ten years, making himself during that period honourably conspicuous by his charities and extraordinary liberality of sentiment. He was at length deposed from all his ecclesiastical functions, on account of his occasional attendance at the parish church of Cullen, between the minister of which and himself there existed an intimate acquaintance. G. now resolved to betake himself to literature, and proceeded to London in 1780. He had long planned a translation of the Bible into English for the use of Roman Catholics, and he was now, through the munificence of Lord Petre, enabled to devote himself to the work. After various preliminary publications intended to pave the way for an impartial or favourable consideration of his *magnum opus*, there appeared in 1792 *The First Volume of the Holy Bible, or the Books accounted Sacred by Jews and Christians, otherwise called the Books of the Old and New Covenants, faithfully translated from Corrected Texts of the Originals, with Various Readings, Explanatory Notes, and Critical Remarks*. In 1793, the second volume was published, carrying the translation as far as the end of the historical books; and in 1800, a third volume was issued, containing his *Critical Remarks on the Hebrew Scriptures*. The opinions enunciated in these volumes, especially in the last, are startlingly heretical, more especially when the training of their author is considered, and were calculated, at the time of their appearance, to offend both Catholics and Protestants. They exhibit as thorough-going Rationalism as is to be found in Eichhorn or Paulus. Moses is said to be inspired in the same sense as other good

men; and in regard to his purpose, it is affirmed that 'he only did what all other ancient legislators had done—required a greater or less degree of implicit obedience to their respective laws, and for that purpose feigned an intercourse with the Deity, to make that obedience more palatable to the credulous multitude.' Miracles are explained away; and the account of the creation in Genesis is described as 'a most beautiful mythos or philosophical fiction, contrived with great wisdom, and dressed up in the garb of real history.' These opinions naturally enough exposed him to the charge of infidelity, and his criticisms were described as 'less scurrilous, perhaps, but not less impious than those of Thomas Paine.' All sorts of ecclesiastics united in their condemnation, and the undoubted effect of their hostility was to crush whatever hopes of literary fame G. may have entertained. He died at London, 26th February 1802. It is now generally admitted, even by those who have no sympathy with his views, that G.'s translation is in the main excellent, and that his remarks are often valuable. His labours have unquestionably advanced the science of Biblical Criticism. Among his other productions may be mentioned a poem on the *Confessional*; the *Battle of B—ng—r*, or the *Church's Triumph*, a comic-heroic poem in nine cantos; and *Bardomachia*, or the *Battle of the Bards*.

GEDDES, JANET, known in Scottish ecclesiastical history as 'Jenny Geddes,' has had her name transmitted as the person who took a prominent part in resisting the introduction of the Liturgy or Service-book into the Church of Scotland in 1637. The circumstances were these. Sunday, 23d July 1637, was the day fixed for this innovation, so obnoxious to the Scottish Presbyterians, and an immense crowd filled the High Church of St Giles's, Edinburgh, on the occasion. On the Dean of Edinburgh beginning to read, his voice was lost in a tumultuous shout, and an old woman, said to have been one Jenny G., who kept a green-stall in the High Street, bawling out: 'Villain! dost thou say mass at my lug?' (that is, ear), launched her stool at the dean's head. Universal confusion ensued, and the dean, throwing off his surplice, fled, to save his life. The Bishop of Edinburgh, on attempting to appease the storm, was assailed by a volley of sticks, stones, and other missiles, accompanied by cries and threats that effectually silenced him. This tumult proved the deathblow of the liturgy in Scotland. It has been doubted, however, if there ever was such a person as Jenny Geddes. In 1756, a citizen of Edinburgh, of the name of Robert Mein (who died in 1776), known for his exertions for the improvement of his native city, published a tract called *The Cross Removed, Prelacy and Patronage Disproved*, &c., in which he claims the exploit of Jenny G. for his great-grandmother, 'the worthy Barbara Hamilton, spouse to John Mein, merchant and postmaster in Edinburgh, who, in the year 1637, spoke openly in the church at Edinburgh against Archbishop Land's new Service-book, at its first reading there, which stopped their proceedings, and dismissed their meeting, so that it never obtained in our church to this day.' In the obituary notice of Robert Mein, *Weekly Magazine*, vol. xxxix., and *Scots Magazine*, vol. xxxvi. (1776), this Barbara Hamilton is said to have been descended from the Hamiltons of Bardowie, 'but was better known in our history by the name of Jenny Geddes, though called so erroneously.' Jenny G.'s famous stool is said to have been burned by herself in the bonfires at the cross of Edinburgh at the Restoration, and what has been called hers in the Museum of the Society of Antiquaries at Edinburgh, has no claim

to that name beyond gratuitous conjecture. See *Proceedings of the Society of Antiquaries of Scotland*, vol. iii. part 2, pp. 179, 180.

GEEFS, GUILLAUME, a Belgian sculptor, was born at Antwerp, on the 10th of September 1806. After studying there for some time, he went to Paris, where he worked in the studio of M. Ramey. During the revolution of 1830, he quitted Paris, and returned to Belgium, and soon after executed at Brussels a monument to the memory of the victims of the revolution of 1830. The most important of his other works are a 'Colossal Marble Statue of King Leopold;' 'Monument to Count Frederic de Merode,' now in the cathedral of Brussels; and 'Statue of General Belliard,' both of whom fell in the revolution. He also executed a group entitled 'Le Lion Amoureux,' which was shewn at the Great Exhibition in Paris (1855).—**GEEFS, JOSEPH**, younger brother of the preceding, and born in 1808, has also acquired a reputation as a sculptor. He has executed a number of statues, of which two, 'Metabus' and 'Thierry Maertens,' were shewn at the Exhibition in 1855. In general character, his works bear a considerable resemblance to those of his brother.—**GEEFS, ALOYS**, youngest brother of the preceding, is also known as a sculptor by means of his 'Epaminondas Dying,' 'Beatrix,' and the bas-reliefs for the 'Rubens' of his eldest brother. He died in 1841.

GEEL, JAKOB, a distinguished Dutch scholar, was born at Amsterdam in 1789, and educated at the Athenæum of that city, principally under Van Lennep. After living at the Hague from the year 1811 as a family tutor, he became second librarian at Leyden in 1823, and in 1833 head-librarian and honorary professor. He had made himself meanwhile known as a philologist by editions of Theocritus, with the *Scholæ* (1820), of the *Anecdota Hæmætherusiana* (1826), of the *Scholæ in Suetonium* of Ruhnken (1828), of the *Excerpta Vaticana* of Polybius (1829); and his *Historia Critica Sophistarum Græcorum* (1823) had called forth several treatises on the same subject from German philologists. In 1840, appeared his edition of the *Olympicus* of Dio Chrysostom, accompanied by a *Commentarius de Reliquis Dionis Orationibus*; and in 1846 he issued the *Phænissæ* of Euripides, with a commentary, in opposition to Hermann. All these works, which are written in pure and pleasing Latin, are models of thorough scholarship, as well as of taste and method. G. contributed further to the revival of classical learning in the Netherlands by the establishment, along with Bak, Peorikamp, and Hamaker, of the *Bibliotheca Critica Nova*, in 1825. The national literature is also indebted to him not only for the translation of German and English works into Dutch, but also for original treatises on various æsthetical subjects. He has, moreover, won the gratitude of the learned throughout Europe by his liberality as a librarian, and especially by his valuable *Catalogus Codicum Manuscriptorum, qui inde ab Anno 1741 Bibliothecæ Lugduni Batavorum accesserunt* (1852).

GEELONG, the second city of Victoria, in Australia, stands at the head of the westerly arm of Port Phillip. It is about 40 miles to the south-west of Melbourne, the capital of the colony, with which it has, since 1855, been connected by a railway, the intermediate space being said to be one of the finest levels for the purpose in the world. Telegraphic communication has also been established with Melbourne, Ballarat, and, since 1857, with the other gold-fields. Though the town is built on the harbour of Corio, yet the cargoes of large ships are discharged into lighters at a distance of

six miles. In 1851, were discovered the gold-fields of the neighbourhood. Even before this, G. had become a flourishing place, as one of the principal seats of the wool trade. Between 1846 and 1851, the houses had increased from 257 to 1593, being more than sixfold in five years; while the inhabitants, multiplying in about the same proportion, gave the corresponding results of 1370 and 8291. Again, between 1851 and the beginning of 1854, the population had grown from 8291 to 20,115. Nor had the gold caused the wool to be neglected, of which, in 1853, the exportation amounted to 7,019,900 lbs., as against 9,870,731 sent from Melbourne itself. Before the close of 1860, the annual value of the rateable property was £130,674, yielding an assessment of £17,507, 0s. 4d., or about 2s. 8d. in the pound. During the year last mentioned, the shipping inwards comprised 179 vessels, and 31,285 tons; while, with respect to the shipping outwards, the corresponding returns were 174 and 32,939.

GEFLÉ, an important town of Sweden, chief town of the län of the same name, is situated at the mouth of the river Gefle, on an inlet of the Gulf of Bothnia, about 100 miles north-west of Stockholm. The stream upon which it stands is divided into three branches, forming two islands, which are united by bridges with the right and left banks of the river, and form portions of the town. G. ranks third among the commercial towns of Sweden; Stockholm and Göteborg alone possessing a more extensive trade. The chief buildings are a gymnasium; a castle, imposingly situated; a court-house, which is considered one of the finest in Sweden; a good public library, and an excellent harbour. G. carries on ship-building to some extent, and has manufactures of sail-cloth, linen, leather, tobacco, and sugar. Its exports are iron, timber, tar, flax, and linen; and its imports chiefly corn and salt. Pop. (1855) 9587.

GEHENNA is the Greek form of the Hebrew *Ge-hinnom* ('Valley of Hinnom'), or *Ge-ben-Hinnom* ('Valley of the Son of Hinnom'). This valley, or rather gorge—for it is described as very narrow, with steep and rocky sides—lies south and west of the city of Jerusalem. Here Solomon built a high place for Molech (1 Kings xi. 7), and, in fact, G. would appear to have become a favourite spot with the later Jewish kings for the celebration of idolatrous rites. It was here that Ahaz and Manasseh made their children pass through the fire, 'according to the abomination of the heathen;' and at its south-east extremity, specifically designated Tophet ('place of burning'), the hideous practice of infant sacrifice to the fire-gods was not unknown (Jeremiah vii. 31). When King Josiah came forward as the restorer of the old and pure national faith, he 'defiled' the Valley of Hinnom by covering it with human bones, and after this it appears to have become 'the common cesspool of the city, into which its sewage was conducted, to be carried off by the waters of the Kidron, as well as a laystall, where all its solid filth was collected. Hence, it became a huge nest of insects, whose larvæ or "worms" fattened on the corruption.' It is also said that fires were kept constantly burning here, to consume the bodies of criminals, the carcases of animals, and whatever other offal might be combustible. Among the later Jews, G. and Tophet came to be regarded as symbols of hell and torment, and in this sense the former word is frequently employed by our Saviour in the New Testament. For example, in Mark ix. 47, 48, he says: 'It is better for thee to enter into the kingdom of God with one eye, than having two eyes, to

be cast into hell-fire [Gehenna]; where their worm dieth not, and the fire is not quenched.'

GEIBEL, EMANUEL, one of the most popular of the living poets of Germany, was born at Lübeck, on the 18th October 1816. After receiving the rudiments of education at the high school of his native town, he completed his studies at the university of Bonn. In 1836, he went to Berlin, where he became acquainted with Chamisso, Gaudy, and Kugler. Two years afterwards, he obtained a tutorship in the family of the Russian ambassador at Athens, where he continued to prosecute his scientific and poetical studies. On his return to Lübeck in 1840, he worked up the material he had collected in Greece, and became, in addition, a diligent student of Italian and Spanish literature. Soon after the publication of his first poems, a pension of 300 thalers a year was bestowed upon him by the king of Prussia. G. now resided alternately at St Goar on the Rhine with Freiligrath, at Stuttgart, Hanover, Berlin, and Lübeck; till, in the spring of 1852, he was appointed professor of æsthetics in the university of Munich by the king of Bavaria. In conjunction with Curtius, he published his *Classische Studien* (Bonn, 1840), containing translations from the Greek poets. These were followed in the same year by his *Gedichte* (Berlin, 1840, 28th edit. 1852), the melody, artistic beauty, and decidedly religious tone of which, made them at once great favourites with the Germans. The results of his Spanish studies were the *Spanischen Volkslieder und Romanzen* (Berlin, 1843), which were followed by the *Spanische Liederbuch* (Berlin, 1852), published in conjunction with Paul Heyse. In 1857 appeared his tragedy of *Brunehilde*. His poems are distinguished by fervour and truth of feeling, richness of fancy, and a certain pensive melancholy, and have procured him a popularity—especially among cultivated women—such as no poet of Germany has enjoyed since the days of Uhland.

GEIGER, ABRAHAM, rabbi in Breslau, was born at Frankfurt-on-the-Maine, May 24, 1810. According to old rabbinical practice, his teachers were his father and elder brother, till he reached the age of eleven. After that, having received a more regular education for some years, he went, in 1829, to the university of Heidelberg, and shortly afterwards to that of Bonn. While engaged there in the study of philosophy and of the Oriental languages, he gained a prize for an essay on the Jewish sources of the Koran, which at a later period appeared in print under the title, *Was hat Mohammed aus dem Judenthum aufgenommen?* (Bonn, 1833). In November 1832, he was called as rabbi to Wiesbaden, and there, under the impulse to the scientific study of Judaism which proceeded from Berlin, he devoted himself zealously to Jewish theology, especially in its relation to practical life. In 1835, he joined with several able men in editing the *Zeitschrift für Jüdische Theologie*. The spirit of inquiry, however, with which he discussed prevalent opinions and usages, brought him into collision with the conservative Jews, especially after 1838, when he became assessor of the rabbinate at Breslau; but the great majority of educated men in the sect continued attached to him. It was he who gave the first impulse to the celebrated assemblies of the rabbis, three of which have been held since 1844 at Brunswick, Frankfurt-on-the-Maine, and Breslau. At the second of these he was vice-president, and president at the third. Though G. thus took an active part in the reform movement, he could not abandon his historical point of view, which made him unwilling to break entirely with the past; and therefore he refused a call to be preacher to the

Berlin Reform Society. Besides sermons, pamphlets and numerous contributions to the above-mentioned periodical, G. published some historical monographs, which are distinguished by thoroughness of investigation and many-sided learning. Among these may be mentioned the *Melo Chofnazim* (Berlin, 1840), on Joseph Salomo del Medigo, and the *Hite Haamanim* (Berlin, 1847), on the exegetical school of Northern France. His *Lehr- und Lesebuch zur Sprache der Mischna* (1845) also is of great value to the Oriental philologist. In 1850 appeared the first number of *Studien on Moses-Ben-Maimon*; and in 1851, a translation of the *Divan of the Castilian Abu'l-Hasan Juda ha-Levi*, accompanied by a biography of the poet and explanatory remarks. Besides some specimens of Jewish medieval apologetics, contributed to Breslau's *Jahrbuch* in 1851—1852, G. has more recently published a work on the original text, and the translations of the Bible in their dependence on the development of Judaism (*Urschrift und Uebersetzungen der Bibel in ihrer Abhängigkeit von der inneren Entwicklung des Judenthums*, Breslau, 1857).

GEILER VON KAISERSBERG, JOHANN, a famous pulpit-orator of Germany, was born at Schaffhausen, 16th March 1455; studied at Freiburg and Basel, where he obtained his degree of D.D.; and in 1478 became preacher in the cathedral of Strasburg, where he died, 10th March 1510. G. ranks among the most learned and original men of his age. His sermons, usually composed in Latin and delivered in German, are marked by great eloquence and earnestness; nor do they disdain the aids of wit, sarcasm, and ridicule. Vivid pictures of life, warmth of feeling, and a bold, even rough morality, are their leading characteristics. In fact, G.'s ethical zeal often urged him to a pungency of satire hardly in keeping with modern views of the dignity of the pulpit, but quite congruous with the taste of his own age. His style is vigorous, free, and lively, and in many respects he may be regarded as a sort of predecessor of Abraham a Sancta-Clara. Of his writings, which have now become very rare, may be mentioned *Narrenschiff* (Lat., Strasb. 1511; Ger. by Pauli, 1520), comprising 412 sermons on Sebastian Brant's (q.v.) *Narrenschiff*; *Das Irrig Schaf* (Strasb. 1510); *Der Seelen Paradiess* (Strasb. 1510); *Das Schiff der Pönitens und Busenwirkung* (Augsb. 1511); *Das Buch Granatapfel* (Strasb. 1511); *Christliche Pilgerschaft zum Ewigen Vaterland* (Basel, 1512); *Das Evangelienbuch* (Strasb. 1515); and *Das Buch Von Sünden des Mundes* (Strasb. 1518). Compare Ammon's *G. Von Kaisersberg's Lehen, Lehren und Predigten* (Erl. 1826), and Meick's *Joh. G. Von Kaisersberg. Sein Leben und Seine Schriften in einer Auswahl* (3 vols., Fkf. 1829).

GEJER, ERIC GUSTAF, one of the most distinguished historians of Sweden, was born at Ransätter, in the Swedish len of Wermland, in 1783. He was sent, at the age of 16, to the university of Upsala; and in 1803 he competed successfully for the prize which was that year awarded by the Academy of Stockholm for the best essay on the life and character of the great Swedish administrator, Sten Sture. This was the turning-point of his life, for from this period he began to devote himself with zealous industry to the study of the history of his native country. His assiduity was rewarded by his speedy nomination to a post in the Chamber of the National Archives, and in 1810 he was elected assistant to Fant, the professor of history in the university of Upsala, and in 1817, on the death of the latter, he succeeded to his chair. G.'s early lectures were listened to with the

profoundest interest, both by his students and the public at large, who crowded to his lecture-room; but at a subsequent period of his teaching, his popularity diminished in proportion to the increased profundity of his views; while the suspicion that he harboured sceptical notions in regard to the Trinity, brought him into disfavour with a certain portion of the community. These suspicions led to his denunciation to the university authorities; but the examination to which the charges against him gave rise terminated in his acquittal, and were even followed by the offer of a bishopric, which, however, he declined. G. exercised a marked influence on the poetic no less than the historical literature of Sweden, and according to the testimony of his countrymen, his *Sista Skalden, Vikingen, Odalbonden*, and other heroic pieces, place him in the foremost rank of Swedish poets. He and his friends Adlerbeth, Tegner, and Nikander, adhered to the 'Gothic' school of poetry, which owed its origin to 'the Society of the Goths,' which they and several of their friends established as early as 1810, when they brought out in connection with it a magazine entitled the *Iduna*, in which first appeared several of G.'s best poems, and among other productions of merit, the early cantos of Tegner's *Frithiof*. Great as is the value of G.'s historical works, he unfortunately did not complete any one of the vast undertakings which he planned. Thus, for instance, of the *Svea Rike's Håfder*, or Records of Sweden, which were to have embraced the history of his native country from mythical ages to the present time, he finished only the introductory volume. His next great work, *Svenska Folkets Historia*, which was intended to form one of the series of European histories, edited by Leo and Uckert, was not carried beyond the death of Queen Christina; yet incomplete as they are, these works rank among the most valuable contributions to Swedish history. To G. was intrusted the task of examining and editing the papers which Gustavus III. had bequeathed to the university of Upsala, with the stipulation that they were not to be opened for fifty years after his death. In fulfilment of his charge, G. arranged these papers in a work, which appeared in 1843 under the title of *Gustaf III.'s efterlemnade Papper*, and which, from the worthless nature of the contents, disappointed the expectations of the nation, who had been led to hope that their publication would reveal state secrets of importance. During the last ten years of his life, G. took an active part in politics; but although his political writings possess great merit, the very versatility of his powers diverted him from applying them methodically to the complete elaboration of any one great object. G. was known to his countrymen as a musician and composer of no mean order. He lived on terms of friendly intercourse with Bernadotte, and his numerous letters to the king form part of the *Samlade Skrifter*, or collective works, which have been published since his death by his son, who has appended to this edition, which was completed in 1853, an interesting biographical sketch of his distinguished father. G. died in 1847.

GELA, in ancient times, a very important town, on the southern coast of Sicily, on the river of the same name. It was founded by a Rhodian and Cretan colony, 690 B.C. Its rapid prosperity may be inferred from the circumstance, that as early as the year 582 B.C., Agrigentum was founded by a colony from Gela. After Cleander had made himself tyrant in the year 505 B.C., the colony reached its highest pitch of power under his brother Hippocrates, who subdued almost the whole of Sicily, with the exception of Syracuse. Gelon, the successor of Hippocrates, pursued the same career of conquest, and

Syracuse itself fell into his hands, and was even made his principal residence, G. being committed to the government of his brother Hiero. After many vicissitudes during the Carthaginian wars in Sicily, it ultimately fell into decay. Its ruin was completed by Phintias, tyrant of Agrigentum, who, a little before 280 B.C., removed the inhabitants to a town in the neighbourhood, which he had founded, and to which he gave his own name. Its site is generally believed to be occupied by Terra Nova, at the mouth of the river now known as Fiume di Terranova.

GELATIGENOUS TISSUES AND GELATINE. The gelatigenous tissues are substances resembling the proteane-bodies (albumen, fibrine, and caseine) in containing carbon, hydrogen, nitrogen, oxygen, and sulphur; but differing from them in containing more nitrogen and less carbon and sulphur. They consist of two principal varieties, viz., those which yield gluten (or ordinary *gelatine*) and those which yield *chondrine*.

Gluten is obtained by more or less prolonged boiling with water, from the organic matter of bone (the *osseine* of Frémy), from tendons, skin, cellular tissue, white fibrous tissue, the air-bladder and scales of fishes, calves' feet, hartshorn, &c.; while chondrine is similarly obtained from the permanent cartilages, from bone-cartilage before ossification, from enchondromatous tumours, &c.

Neither gluten nor chondrine appears to exist *as such* in the animal body, but is in all cases the result of the prolonged action of boiling water on the above-named tissues. Frémy's analyses (see his *Recherches Chimiques sur les Os*, in the *Ann. de Chim. et de Phys.*, 1855, vol. xliii., p. 51) shew that *osseine* is isomeric with the gluten which it yields, and further, that the amount of gluten is precisely the same as that of the *osseine* which yields it.

The following table exhibits the composition of *osseine* and the gluten yielded by it as determined by Frémy, and that of chondrine as determined by Mulder:

	<i>Osseine</i>	Gluten.	Chondrine.
Carbon,	49.21	50.40	49.97
Hydrogen,	6.50	6.50	6.63
Nitrogen,	17.86	17.50	14.14
Oxygen with a little Sulphur,	25.14	25.00	28.27

Gluten, when perfectly pure and dry, is a tough, translucent, nearly colourless substance, devoid of odour and taste. It swells when placed in cold water, and loses its translucency; but in boiling water it dissolves, and forms a viscid fluid, which on cooling forms a jelly. A watery solution containing only 1 per cent. of gluten, gelatinises on cooling. This property is destroyed both by very prolonged boiling and by the action of concentrated acetic acid. Gluten is insoluble in alcohol and in ether.

A solution of gluten is abundantly precipitated by solutions of corrosive sublimate and of bichloride of platinum, as well as by infusion of galls, of which the active principle is tannin or tannic acid (the terms being synonymous). Tannic acid produces, even in very dilute solutions, a copious yellow or buff-coloured precipitate of tannate of gluten. The gelatigenous tissues unite in a similar manner with tannin; they extract it from its watery solutions, and form compounds with it which resist the action of putrefaction. It is thus that hides are converted into Leather (q.v.). The tests which we have mentioned also precipitate albumen, but gluten may be distinguished from albumen by its not being thrown down (as is the case with albumen) by the addition of ferro-cyanide of potassium together with a little acetic acid. The gelatinising property also serves to distinguish gluten when it amounts to 1 per cent. or more of the solution.

On exposure to the atmosphere, gluten becomes

GELATINOGENOUS TISSUES—GELATINE

more rapidly putrid than almost any other animal substance. Under the influence of oxydising agents, it yields the same products as the proteine-bodies; treated with the mineral acids or with alkalies, it yields Glycoccine (q. v.)—known also as glycine, glyccoll, and sugar of gelatine—Leucine (q. v.), and other products.

Isinglass, which is prepared from the air-bladder of the sturgeon, &c., when boiled with water, furnishes gluten in a nearly pure state. Glue and size are two well known forms of impure gluten or gelatine.

Chondrine resembles gluten in its physical properties, and especially in its property of gelatinising. It differs, however, slightly from it in chemical composition (see the above table), and in its behaviour towards reagents. For instance, acetic acid, alum, and the ordinary metallic salts of silver, copper, lead, &c., which produce no apparent effect on a solution of gluten, throw down a precipitate from a solution of chondrine; while, on the other hand, corrosive sublimate, which precipitates gluten freely, merely induces a turbidity in a solution of chondrine.

We do not know much regarding the physiological relations of these substances. Gluten (according to Scherer) usually exists in the juice of the spleen, but in no other part of the healthy animal body; it is sometimes found in the blood in cases of leucocythæmia, in pus, and in the expressed juice of cancerous tumours. Chondrine has been found in pus. The gelatinous tissues rank low in the scale of organisation, and their uses are almost entirely of a physical character. Thus they form strong points of connection for muscles (the tendons), they moderate shocks by their elasticity (the cartilages), they protect the body from rapid changes of temperature by their bad conducting power (the skin), and they are of service through their transparency (the cornea).

GELATINE, in Technology. This term, although usually applied to only one variety of the substance, obtained by dissolving the soluble portion of the gelatinous tissues of animals, nevertheless properly belongs also to **ISINGLASS** and **GLUE**, which are modifications of the same material. Vegetable jelly is also analogous, and will be mentioned under this head.

Gelatine and glue signify the more or less pure and carefully prepared jelly of mammalian animals, but the term isinglass is only applied to certain gelatinous parts of fishes, which from their exceeding richness in gelatine, are usually merely dried and used without any other preparation than that of minute division for the purpose of facilitating their action.

GELATINE (proper) is prepared for commercial purposes from a variety of animal substances, but chiefly from the softer parts of the hides of oxen and calves and the skins of sheep, such as the thin portion which covers the belly, the ears, &c.; also from bones and other parts of animals.

One of the best, if not the best of the varieties of gelatine manufactured in Great Britain, is that made by Messrs Cox of Gorgie, near Edinburgh, which is remarkable for its great purity and strength, or gelatinising power; they call it 'sparkling' gelatine from its beautiful bright transparency, and its purification is effected by certain processes which they have patented. The materials they use are carefully selected portions of ox and calf hides. Another preparation, made by Mr Mackay of Edinburgh (pharmaceutical chemist), is deserving of special mention, as it is prepared with the greatest care from calves'-feet, and is especially adapted for invalids. It is made on a limited scale, and only for a few leading chemists.

The general method adopted with skin-parings or hide-clippings, is first to wash the pieces very carefully; they are then cut into small pieces and placed in a weak solution of caustic soda for a week or ten days, the solution being kept moderately warm by means of steam-pipes. When this process of digestion has been sufficiently carried on, the pieces of skin are then removed into an air-tight chamber lined with cement, and here they are kept for a time, determined according to the skill of the manufacturer and the kind of material employed, at a temperature of 70° F. They are next transferred to revolving cylinders supplied with an abundance of clean cold water, and afterwards are placed still wet in another chamber lined with wood, in which they are bleached and purified by exposure to the fumes of burning sulphur; they next receive their final washing with cold water, which removes the sulphurous acid. The next operation is to squeeze them as dry as possible, and transfer them to the gelatinising pots, which are large earthen vessels, enclosed in wooden cases, made steam-tight. Water is poured in with the pieces, and kept at a high temperature by means of the steam in the cases surrounding the pots.

By this means the gelatine is quite dissolved out of the skin, and is strained off whilst still hot; it is poured out in thin layers, which as soon as they are sufficiently cooled and consolidated, are cut into small plates, usually oblong, and laid on nets, stretched horizontally, to dry. The cross-markings observable on the plates of gelatine, in the shops, are the marks left by the meshes of the nets.

Another process, introduced by Mr Swineburne, consists in treating pieces of calf-skin by water alone, without the soda and sulphur processes; the pieces, after simple washing, being transferred at once to the pots to be acted upon by the steam; undoubtedly, this is the purest, but the expense of preparing it prevents its general use. Inferior gelatine is made from bones and other parts of animals, and it was stated by an eminent authority, that in Paris the enormous number of rats which are occasionally killed in the sewers and abattoirs, after being deprived of their skins, which are reserved for other purposes, are all used by the gelatine-makers. These materials are placed in cages of wire, which are placed in steam-tight boxes, where they are submitted to the direct action of steam of 223° F., but at a low pressure; and cold water, supplied by another pipe through the upper part of the box, is allowed to flow slowly and percolate through the contents of the cage, the water and condensed steam descend to the bottom charged with gelatine, and are drawn off by a stop-cock placed there for the purpose.

The French manufacturers succeed better than any others in clarifying these inferior gelatines, and they rarely make any others; they run their plates out very thin, which gives them greater transparency and apparent freedom from colour; and they colour them with most brilliant colours, and form very fine-rolled sheets, tempting the eye with an appearance of great delicacy and purity, which would at once disappear if the material were made up into the thicker plates of the British manufacturers.

The purity of gelatine may be very easily tested; thus: pour upon dry gelatine a small quantity of boiling water, if pure it will form a thickish gluey colourless solution, free from smell; but if made of impure materials, it will give off a very offensive odour, and have a yellow gluey consistency. No article manufactured requires such careful selection of material and such nice and cleanly manipulation to insure a good marketable character; and those

GELATINE.

anxious for purity should avoid all artificially coloured varieties, however temptingly got up, unless they are required for merely decorative purposes and not for food. For the value of gelatine as food, see DIET.

ISINGLASS (supposed to be derived from the German *Hauseblase*, bladder of the sturgeon), the *Ichthyocolle* (*ichthus*, a fish; *kolla*, glue) of the classical and scientific writers, was formerly obtained only from the common sturgeon (*acipenser sturio*), and consisted of the dried air-bladder of the animal. The necessities of modern commerce have, however, led to the discovery, that the same part in many other fishes forms good isinglass; and instead of Russia, as formerly, being almost the only producing country, we have now large quantities from South America, chiefly imported from Maranham, some from the East Indies, the Hudson's Bay Territory, New York, and, owing to Professor Owen calling the attention of the Canadian Commissioners of the Exhibition of 1851 to the subject, it is now brought in considerable quantities and of excellent quality from Canada, where it is likely to prove a source of profitable industry.

The commercial varieties of this material are numerous, and a thorough knowledge of them can only be obtained by considerable personal acquaintance with them; therefore, their names only are given, with those of the producing animals:

Besides these now well-known commercial varieties, others are occasionally met with, as the *Manilla*, in thin cakes; the *Para*, which is the most remarkable of all, resembling grapes of a reddish-brown colour, growing from a straight thick stem; these are the dried ova of the *Sudis gigas*, a large fish common in the mouths of the Amazon. An inferior kind is also made of cod-sounds and sole-skins, sufficiently good, however, to be used in fining beer and other liquids.

One of the qualities of gelatine is its power to form chemical combinations with certain organic matters; hence, when it is mixed and dissolved in a fluid containing such matters, it combines, and the compound is precipitated. It would appear

that this combination, however, is threadlike in its arrangement, and that the crossing threads form a fine net-work through the fluid, which, in falling, carries down all floating substances, which, by their presence, render the liquid cloudy; hence its great value in clarifying beer and other liquids. For this reason isinglass, which has been found the best gelatine for the purpose, is very largely consumed by brewers.

Isinglass, strictly speaking, is not gelatine, but its only value is from the excessive proportion of gelatine held in the tissues of the organ which yields it, greatly enhanced by the ease with which it is abstracted from the membrane when compared with the complicated process necessary for separating and purifying the gelatine from the skins, &c., of other animals. When separated, however, the substances are identical in composition, and, if pure, are undistinguishable from each other.

Besides the substances mentioned as yielding gelatine, formerly hartshorn shavings were used, and ivory turnings and saw-dust are still employed, both, however, chiefly for dietetic purposes for invalids; and various kinds of animal food are valued for the abundance of gelatine they contain, as the Trepang and Beche de Mer (species of *Holothuria*), sharks fins, fish-maws, ray-skins, elephant hide, rhinoceros hide, and the softer parts, all of which are luxuries amongst the Chinese, Japanese, Siamese, Malaya, &c. Turtle-shells, or the upper and lower parts of the shield (*carapace* and *plastron*), constitute the callipash and callipes of the epicure, and form, in the hands of the experienced cook, a rich gelatinous soup. The fleshy parts of the turtle, calves' head and feet, and many other things, might be enumerated as valuable, chiefly in consequence of their richness in this material.

GLUE differs only from *gelatine* in the care taken in its manufacture, and in the selection of the materials from which it is made; almost every animal substance will yield it, hence all kinds of animal refuse finds their way to the glue-makers' boilers. Nevertheless, the impossibility of preserving, for any length of time, the materials required for this manufacture, renders it necessary to adopt some system in choosing and preserving them, until sufficient quantities are collected, without fermentation or decomposition. Hence the refuse of tanneries, consisting of the clippings of hides, hoofs, ear and tail pieces of ox, calf, and sheep are preferred, because they can be dressed with lime, which removes the hair, and acts as an antiseptic. For this purpose, they are placed in tanks with quicklime and water for two or three weeks, during which the lime is several times renewed, and the pieces frequently turned over. They are afterwards washed and dried, and are ready for use by the glue-maker, who usually gives them another slight lime-dressing, and subsequently washes them; they are afterwards exposed to the action of the air for a time, to neutralise the caustic lime. When well-drained, the pieces are placed in flat-bottomed copper-boilers, which have a perforated false bottom placed a little distance above the true one, to prevent the burning of the materials, and which have been supplied with rain or other soft water up to two-thirds the depth of the boiler, the pieces being piled up to some height above the top of the open boiler. The whole is kept at a gentle boiling heat until all the gelatinous part has dissolved out, and the mass of material has sunk down into the fluid. The boiling is sustained until, by repeated trials of small quantities, the operator knows the fluid is of the right consistency, when it is drawn off carefully into the congealing boxes, and fresh

* So called from the bladder being purposely bent into the form of a staple in drying.

materials are added to the residue left behind in the boiler, and the process is repeated.

The congealing boxes are of wood, and are nearly square, being slightly narrower at the bottom than the top; they are filled to the brim, and when their contents are sufficiently solidified, the glue, with a little management, turns out in the form of a cube, which is cut into thin slices by a wire in the same manner as soap; and these larger slices are subdivided into smaller cakes by a wet knife. Frames, with nets stretched upon them, are provided for drying the cakes upon; and these frames, when covered with the cakes of glue, are adjusted one over another at a little distance apart, supported between four uprights, and if in the open air, covered over with little wooden roofs, the whole being arranged so that the air can have free access to facilitate drying. This process is an anxious one to the manufacturer, as the changes of the weather have great and often completely destructive effects upon glue in this state; and in this country only the spring and the autumn can be relied upon with any satisfaction. Generally, after the open air drying, the glue is taken to drying-rooms heated slightly, where it hardens effectually; but it is not yet finished; the cakes at this stage have a dull, unsightly look, to remedy which they are dipped into cold water, or are wetted with a brush dipped in hot water, and re-dried, this wetting giving the cakes a bright varnished appearance. Great Britain does not excel in the manufacture of glue, and British workmen usually prefer the dark variety. Very superior glue is made by the Dutch and Germans, by whom the light and more carefully made varieties are most prized, the adhesive qualities being lessened exactly in proportion to the impurities present in the material.

Besides its use in joinery, cabinet-making, and similar operations, glue is used by paper-makers and in dressing silks; and for these last two purposes fine light-coloured kinds in thin cakes are made. Large quantities are employed also by paper-hangers and others for sizing walls in the state called *siz*, which is the glue simply gelatinised after boiling in the first process. A very fine and pure white *siz* is made by the bonnet-makers of Bedfordshire and other places of the skins of calves' head, ears, and the under part of the neck and belly: this is used for stiffening straw, cotton, horse-hair, and other plaits for making bonnets and hats.

VEGETABLE JELLY, which is analogous to animal gelatine, is obtained largely from some fruits, but never in a pure state; it is only of value in preserving such parts of the fruit for culinary purposes; but several of the sea-weeds yield a large quantity of very pure jelly, which, in some instances, is applied to important purposes: thus, the jelly of *Fucus spinosus*, the agar-agar, or agal-agal, abundant on the shores of the eastern seas, is used by the East Indians, Cingalese, and Chinese for dressing their silks; the Chinese also ingeniously form thin films of the jelly over a framework of bamboo, and thus make small windows for their houses. This, and another, *Gracillaria lichenoides*, are formed into a thick jelly, with sugar and other materials, and eaten as a delicacy; and both are supposed to supply the material for those wonderful birds' nests, which constitute the most costly luxury known to the art of cooking. Another jelly-yielding sea-weed is found on our own shores, called the Irish Moss or Carrageen (*Chondrus crispus*), which is often made into jellies for invalids, and the plant itself, on account of its richness in this material, is very extensively employed in feeding cattle, especially in England.

GELDERLAND, a province of Holland, is situated between the Zuider Zee on the north-west, and the Prussian dominions on the south-east. It has an area of 1948 square miles, and in 1860 a population of 405,490. It is watered chiefly by the Yssel, the Rhine, the Waal, and the Maas. The surface is in general flat, but northward from Arnheim, the capital, and over the whole of the north-west portion of the province, stretch sandy hills, frequently covered with bushes. The climate is healthy, and the soil, on the whole, good, though much of it is still in heath and marsh. Along the river valleys a rich loamy soil is found. Agriculture is prosecuted with great success. Wheat, rye, buckwheat, tobacco, &c., are abundantly produced. Among the manufactures, paper and leather are the principal. Chief towns, Arnheim, Nimeguen, and Zutphen.

GELIDIUM, a genus of *Algæ* (sea-weeds), of the sub-order *Ceramiceæ*, some of the species of which are believed to afford the material used by certain species of swallow in building the edible nests so much prized by the Chinese. See NESTS, EDIBLE. Several species of gelidium are used as food in the east. Like many other sea-weeds of this order, they are almost entirely gelatinous, and when boiled with condiments to give pungency and flavour, form a very wholesome and agreeable food.

GELL, SIR WILLIAM, knight, an eminent antiquarian and classical scholar, the younger son of Philip Gell, Esq. of Hopton, Derbyshire, was born in 1777. He was educated at Jesus College, Cambridge, where he graduated as B.A. in 1798, and M.A. in 1804, and was for sometime a fellow of Emmanuel College in that university. He devoted his time principally to antiquarian research and geographical studies, and published the following learned and valuable works: *The Topography of Troy* (1804, folio); *The Geography and Antiquities of Ithaca* (1808, 4to); *The Itinerary of Greece* (1810, 4to); *The Itinerary of the Morea* (1817, 8vo); *Attica* (1817, folio); *Pompeiana, or Observations upon the Topography, Edifices, and Ornaments of Pompeii*—in conjunction with J. P. Gandy, Esq., an interesting and beautiful work, which first brought his name into notice (2 vols. 8vo, 1817—1819; second series, 2 vols. 8vo, 1832); *Narrative of a Journey in the Morea* (1823, 8vo); *The Topography of Rome and its Vicinity* (1834, 8vo); *Rome and its Environs* (Map, 1834). In August 1814, on the departure to the continent of Caroline, Princess of Wales, consort of George IV., she appointed him as one of her chamberlains. In that capacity he attended her in various parts of Italy, but being attacked with the gout, was soon obliged to resign his situation. In 1820, he was examined as a witness at the bar of the House of Lords during the proceedings against her majesty after she became queen, and had returned to England. Subsequently, he resided in Italy, principally at Naples, having a house also at Rome, where he occasionally took up his abode. He died at Naples, February 4, 1836, and was interred in the English burial-ground of that city.

GELLERT, CHRISTIAN FÜRCHTEGOTT, a German poet and moralist, was born July 4, 1715, at Haynichen, in the Erzgebirge, in Saxony, entered the university of Leipzig in 1734, where he devoted himself mainly to the study of theology. After some years spent as a tutor, and as a teacher in a public academy, he obtained a professorship in the same university in 1751. His lectures on poetry, rhetoric, and morals were numerously attended, and were greatly admired. He died 13th December

1769. G. was a man of spotless virtue, but rather effeminate in mind and character. He wrote fables, stories, didactic poems, spiritual odes and songs. His most popular writings were his fables and stories. They are marked by ease and naturalness of manner. His spiritual odes owe their continued popularity to their deep piety, and to a certain vigour and loftiness of flight not to be found in his other poems. G. is to be considered one of the pioneers of modern German literature. He marks, along with others, the transition from the dulness and pedantry of the previous generation of authors, to that rich and superabundant life which Goethe and Schiller poured into the national literature. G.'s collective works (*Sämmtliche Werke*) first appeared at Leipzig in 10 vols. (1769—1774), and have passed through various editions; the most recent is that published in the same city (6 vols., 1840—1841). Compare *Gellert's Leben*, by J. A. Cramer (Leip. 1774), and by Döring (2 vols., Leip. 1833).

GELLIUS, AULUS, a Latin author, who seems to have lived about 117—180 A.D. The exact date, either of his birth or death, is not known. He is supposed to have been born at Rome, where, at all events, he studied rhetoric. Subsequently, he proceeded to Athens to undergo a discipline in philosophy. On his return to Rome, he entered upon a legal career, without, however, abandoning his literary pursuits. G.'s well-known work, the *Attic Nights* (*Noctes Atticæ*), begun during the long nights of winter in a country-house near Athens, and completed during the latter years of his life, is a collection of miscellaneous matter on language, antiquities, history, and literature, in 20 books, of which the 8th is wanting. It contains many extracts from Greek and Latin authors no longer extant. The work is destitute of any plan or arrangement, is disfigured by archaisms, and derives its value mainly from being a repository of curious knowledge. The *Editio Princeps* appeared at Rome in 1469; the most critical edition is that of Jak. Gronovius (Lug. Bat. 1706); a more recent but much less valuable one is that of Lion (2 vols., Göttingen, 1824—1825). G. has been translated into English by Beloe (Lond. 1795); into French by the Abbé de Verteuil (Paris, 1776); and (in part) into German by Von Walterstern (Lemgo, 1785).

GELON, 'tyrant' of Gela and Syracuse, was the son of Deinomenes, and was a native of the former city. His family was one of the oldest and most distinguished in the place. G. himself first figures in history as one of the body-guards in the service of Hippocrates, tyrant of Gela. On the death of the latter, he contrived to obtain the supreme power (491 B.C.), and about 485 B.C., he made himself master of Syracuse also, which then became the seat of his government, and to which he transferred the majority of the inhabitants of Gela. His influence soon extended itself over the half of Sicily. G. refused to aid the Greeks against Xerxes, as they declined to comply with his demand that he should be appointed commander-in-chief. About the same time, Terillus, ruler of Himera, in Sicily, invoked the aid of the Carthaginians against Theron of Agriguntum, who had dispossessed him of his state. G., who was in alliance with Theron, hastened to the assistance of the latter, and on the same day (according to tradition) on which the Greeks won the battle of Salamis, he gained a complete victory over the invaders at Himera. The consequence was an immediate treaty of peace between him and the Carthaginians, who were compelled to pay all the expenses of the war. His clemency and the wisdom of his measures rendered him so generally beloved,

that when he appeared unarmed in an assembly of the people, and declared himself ready to resign his power, he was unanimously hailed as the deliverer and sovereign of Syracuse. The story current in later times, that one of the conditions on which he granted peace to the Carthaginians was, that their human sacrifices should be abolished, has probably no historical foundation, but it illustrates the general belief in the humanity of his character. G. died 478 B.C. The people, who, contrary to his desire, had erected a splendid monument to his memory, paid him honours as a hero, and at a later period, when all the brazen statues were sold under Timoleon, his statue was made an exception to the general rule. He was succeeded by his brother Hiero.

GEM, a term often used to signify a precious stone of small size, such as may be used for setting in a ring, or for any similar purpose of ornament; but sometimes by mineralogists in a sense which they have themselves arbitrarily affixed to it, for the purpose of scientific classification, as the designation of an *order* or *family* of minerals, generally hard enough to scratch quartz, insoluble in acids, infusible before the blow-pipe, without metallic lustre, but mostly brilliant and beautiful. Among them are included some of the minerals, which, in popular language, are most generally known as gems—ruby, sapphire, spinel, topaz, beryl, emerald, tourmaline, hyacinth, zircon, &c.—and some other rarer minerals of similar character; but along with these are ranked minerals, often coarser varieties of the same species, which are not *gems* in the ordinary sense of the word, as emery and common corundum, whilst diamond and some other precious stones, much used as gems, are excluded. See GEMS.

GEMARA (Ghemára, a Chaldee word, signifying complement) is that portion of the two Talmuds which contains the annotations, discussions, and amplifications of the Mishnah by the academies of Palestine on the one hand, and those of Babylon on the other. The Babylonian Gemara, more complete as well as more lucid than the Palestinian, possesses a much more highly valued authority. The final redaction of this latter falls in the middle of the 4th c. A.D., while the former was not completed till 500 A.D. See MISHNAH and TALMUD.

GEMINI (the Twins), the third constellation in the zodiac, named from its two brightest stars, Castor, of the first magnitude, and Pollux, of the second.

GEMISTUS, GIORGIOS, called GIORGIOS PLETHON, and more commonly GEMISTUS PLETHON, was the last of the Byzantine writers. The exact dates of his birth and death are uncertain, but he is known to have lived between 1350 and 1450. He was probably born at Constantinople, but the greater part of his life was passed in the Peloponnese. He was one of the deputies sent by the Greek church to the council which was held at Florence in 1438, for the purpose of arranging a union between the Latin and Greek churches. The council, however, entirely failed in its purpose. G. was more celebrated as a philosopher than as a theologian. In his time, the Aristotelian philosophy reigned supreme, but it had degenerated into a mere science of words, from the study of which G. turned away disgusted, and applied himself to Plato. Plato's philosophy so charmed him, that thenceforward he devoted himself to its propagation; and in furtherance of this view, G., when in Italy, induced Cosmo de Medici to embrace it. Cosmo's example was followed by others in Florence, and

thus a Platonic school was founded in the west which flourished for nearly 100 years afterwards. During the latter part of his life, G. was engaged in bitter conflict with the most eminent of the Aristotelians, among whom George of Trebizond held a high position, and between him and G. the discussion was carried on with most unseemly violence. G. is last heard of in history in 1441, when we find him in the Peloponnesus in an official capacity. G. wrote a great number of works in history, philosophy, theology, &c.

GEMMATION, or GEMMIPAROUS GENERATION. See REPRODUCTION.

GEMOTE. Besides the great council of the nation—the *Witena-gemot*, or, as we more usually spell it, *Witenagemote* (q. v.)—which corresponded to the Reichstage of the Franks, and which, though it took the place of the still more ancient meetings of the whole nation, to which Tacitus refers as characteristic institutions of the Teutonic tribes in his day, was a representative, though not perhaps an elective body (Kemble's *Saxons in England*, ii. p. 194), there were amongst the Anglo-Saxons various minor motes or moots, which did not partake of the representative character. The existence of these is an instance of the manner in which the spirit of localisation has always maintained its ground, and balanced that of centralisation amongst the Germanic nations, and more particularly in England. There was the *shire-gemot*, or county court, which met twice a year; and the *burg-gemot*, which met thrice; the *hundred-gemot* (see HUNDRED), which met every month, and an extraordinary meeting of which was held twice a year; the *hallengemote*, or *court-buron*. These institutions excluded not only central despotism, but local tyranny in the shape of individual caprice. The ealdorman decided only with the assent of the shire-gemote, just as the king was dependent upon that of the *Witan*. Lappenberg by Thorpe, ii. p. 322.

GEMS, ANCIENT. The term *gem*, which is applied to jewels and other valuable and precious stones, means in archaeology engraved stones of the precious kinds, and even small engraved portions of hard and primitive rocks which have been set or worn as jewels by the ancients. Before entering, however, upon the subject of engraved stones, it will be necessary to mention the principal kinds which are mentioned by ancient authors, or have been found by modern researches to have been used for engraving.

Although the principal varieties of precious stones were known to the ancients, yet owing to the absence of scientific and chemical analysis, they appear to have distinguished precious, and other stones, only by colour, specific gravity, and density. The different nomenclature, too, used by different authors, multiplied synonyms, and caused confusion; so that it has become impossible to identify all the stones mentioned by Theophrastus, Pliny, and others. As a general rule, the ancients did not engrave such precious stones as the diamond, ruby, and sapphire, being content with those of less hardness and value. The principal stones used by engravers were: (1) The carnelian, and its more transparent variety the *sard*, *sardion*, in common use in the days of Plato (so called from Sardes in Lydia, but chiefly obtained from India and Babylonia); (2) The chalcedony, supposed to be the ancient chalcedonium, used for seals and reliefs, of which two kinds have been found: (3) The *onyx* or nail-stone, variously described by Pliny and his predecessors, but distinguished by a white layer resembling the nail: (4) The *nicolo* or *Ægyptilla*, obtained from the *onyx*, a blue spot with a

black zone encircling it: (5) The *sardoniz*, which was a variety of the *onyx*, having black, blue, white, and red colours, and particularly used for cameos and vases, by cutting down the lighter coloured layers to the darkest for a background to the figures, a stone much prized by the ancients; the signet of Scipio Africanus the Elder being of this material, and the Emperor Claudius esteeming it and the emerald above all other gems: (6) The *agate* or *achates*, so named from a Sicilian river, embraced many varieties, as the *jaspachates*, *dendryachates*, but confounded with the *jasper*, considered a charm against scorpions and spiders, used for whetstones, and a talisman by athletes; it was obtained from Egypt, Greece, and Asia: (7) *Plasma* or the *Prasus*, root of emerald, much used under the lower empire; its varieties were the *Molochates* and *Nilon*: (8) Numerous varieties of the *jasper*, *iaspis*, green, blood-red, yellow, black, mottled or porcelain, and even blue, were employed for signets at the Roman period, and procured from India, Persia, and Cappadocia. Pliny mentions a remarkable statuette of Nero, weighing 15 ounces in this material: (9) *Garnets*, the *granatici* or red hyacinths of antiquity, which were principally in use at the latter days of the Roman empire, and amongst the Oriental nations—with which may be classed: (10) The *carbunculus*, supposed, however, by some to be the name given by the ancients to the ruby, was brought from India, Garamantia, Carchedon, and Anthemusia: (11) The *hyacinthus* or *jacinth*, a yellow variety of the garnet, which was used for signets, and came from Ethiopia and Arabia: (12) The *Lyncurium*, or *Lychnis*, which is the ancient name of the true modern jacinth: (13) Several varieties of the emerald or *smaragdus* are cited by the ancients, as the Bactrian or Scythian, supposed to be a green ruby, principally derived from the emerald mines at Zabara, in the neighbourhood of Coptes, worked by consecrators, and described by Agatharceides. Many remarkable stories are told of this gem, which has only been found with engravings of a later period; one sent by a king of Babylon to a king of Egypt was 4 cubits long and 3 in width; an obelisk in the temple of Jupiter, 40 cubits high, is said to have been made out of four emeralds; and Theophrastus mentions an emerald column of great size in the temple of Hercules at Tyre. In the Egyptian labyrinth, according to Apion, was a colossal Serapis of great height, made of emerald. This stone was used by gem-engravers to 'refresh' the sight, or inlaid in the eyes of statues, as in the Lion at Cyprus, erected to Hermias; it was set in the ring of Polycrates; and used as a lens by Nero to behold the fights of the gladiators in the circus: (14) The *Beryl* or *Beryllus*, obtained from India, cut in shape of a hexagonal pyramid, was used at an early period for engraving: (15) The *amethyst*, brought from Arabia Petraea and Armenia Minor, is found used for intagli at all periods: (16) The *sapphirus* of the ancients, supposed by some to be *lapis lazuli*, came from Media, and appears in use amongst the Egyptians and Persians: (17) The *anthrax*, supposed to be the ruby, was not engraved; the *hyacinthus* has also been conjectured to be the blue sapphire: (18) The *topas*, *topazon*, applied by the ancients to a green stone found by the Troglodytes in the island of Cytis, in the Arabian Gulf, and first sent by Philemon to Berenice, out of which also a statue of Arsinoe was made and placed in the so-called 'golden temple' by Ptolemy Philadelphus: (19) The *Chrysolithus*: (20) *Chrysoprase*, *turquoise callais*: (21) The *magnes* or *loadstone*, were used for cylinders and gems of a late period: (22) The green *tourmaline*, or *avanturine*, *sandaresus*: (23) The obsidian, *obsidianus*,

so-called after its founder Obsidina, four elephants made of which were dedicated by Augustus in the temple of Concord were also known; and a statue of Menelaus, made of the same material, was returned to the Heliopolitans by Tiberius: (24) The *opal opalites*, or *paderos*, obtained from India, the largest of which then known, of the size of a hazel-nut, belonging to the senator Nonius, was valued at about £2000, which he would not yield to M. Antony; this stone was sometimes engraved: (25) The *adamas*, of which seven varieties were known to the ancients, was only used for cutting other gems, or worn rough, but was not engraved, or even faced, the art of polishing it having been discovered by Louis de Berghem in the 15th century. The list of Pliny, indeed, contains many other stones, which have been either confounded with those already described—their names having been derived from different sources—or else they are species of the same. Many of these had fanciful names, as (26) the *Aromatites* of Arabia and Egypt, so-called from its fragrance: (27) The *alectorius*, worn by the wrestler Milo, so-called from being taken out of the gizzard of a fowl. (28) The *asplutea*, a fiery stone, said by Democritus to be found in the nest of Arabian birds. In the selection of stones for engraving, the gem-engravers adapted the material to the subject—Bacchanalian subjects were often engraved on amethysts; marine, on beryls; martial, on carnelians, sarda, and red jaspers; rural, on green jasper; celestial, on chalcedony. Superstitious virtues were also attributed to the different varieties of gems—thus the amethyst was supposed to protect from the influence of wine; and according to Dioscorides, the jasper was particularly adapted for amulets; and Alexander of Tralles recommends the subject of Hercules engraved on a Median stone, to be worn on the finger as a remedy against the ebolic.

The art of engraving precious stones at the earlier periods of the Egyptian monarchy was comparatively unknown, although these people made beads of carnelian, felspar, root of emerald, jaspers, lapis lazuli, amethyst, and other hard stones. For the purposes of seals, however, and for intagli, steatite scarabs were generally used, and engraved gems are either of the greatest rarity or suspected, till the time of the Ptolemies. A remarkable exception to this rule is a square signet of yellow jasper,

Green Jasper Abraxas,
figure of Lao.

engraved with the name and titles of Amenophis II. (about 1450 B.C.) and his horse, in the British Museum. Under the Ptolemies and Romans, the Gnostic gems, called *Abraxas*, generally of lapis lazuli, blood-stone, and jasper, begin to appear, but these are made by the same process as the Greek, from which they were derived. The Ethiopians, according to Herodotus, engraved signets. The same may be said of the

neighbouring Phœnicia, which either imitated the cylinders of the Babylonians, or the scarabs of the Etruscans. In Assyria, the oldest gems are of cylindrical shape, from one to two inches long, and half an inch thick, pierced through their long axis for a cord to attach round the wrist. The earlier ones are of serpentine, the later of the time of Sargon or Shalmaneser, of agate, jasper, quartz, and syenite, engraved with figures of the gods, and the names of their possessors in cuneiform. The inscriptions, indeed, are often difficult to read, but names similar to those of Assyrian and Babylonian monarchs occur,

one cylinder having a name like that of Nebuchadnezzar. The Babylonian are of the same type, and chiefly of hematite, loadstone, steatite, and jasper; have also figures of deities, and the names of deities or the possessors, generally executed in a coarse rude style by the graver. Oval gems, indeed, appear, from the impressions on the clay tablets, to have been in use at the same time; that of cylinders passed to the Persians, under whom the art became much better, and chance has preserved the cylinder signet of Darius I., found in Egypt.

Chalcedony Cylinder: Signet of Darius I.

These cylinders were abandoned for conical gems, principally of chalcedony, engraved on the base with figures of deities, in use prior to the conquest of Alexander, and were at a later period, commencing in the 3d c. A.D., followed by hemispherical agate gems, with heads, animals, and Pehlevi inscriptions, generally of a rude and debased style of art. These, again, at a later period, were succeeded by convex stones or cabochons, often garnets, sarda, carbuncles, engraved on the upper surface, with rude figures of animals, heads and other devices also, accompanied with Pehlevi inscriptions, and these probably continued till the rise of Mohammedanism in the East, when the art was confined to the engraving of cufic legends on the most valuable of oriental stones, often with a great degree of dexterity. In Judea, the use of signets (see SEALS) prevailed, and the most important known instance is the Urim and Thummim, or breastplate of the high-priest, consisting of twelve precious stones, engraved with the names of the twelve tribes; but no Hebrew engraved stones earlier than the 5th or 6th century are known. Amongst the other oriental nations of antiquity, the Bactrians and early Hindus seem to have exercised the art of engraving on stones, although no works of great merit of these nations have been found, and those of a later age are mere seals engraved with sentences of the Koran, or the names of the possessors, and when smeared with black or coloured inks, were impressed on documents as stamps. Of the other nations of antiquity, the Chinese only have had seals (see SEALS) of crystal, soapstone, porcelain, and other substances, with devices in relief for using as stamps, the subjects being mottoes from poetical and other works.

The Greeks, at the earliest period, are not supposed to have employed engraved stones for their signets, the earliest rings being of solid metal, such as the legendary ring of Minos; but at a later period, those of Helen, Ulysses, and the legendary one of Gyges, are said to have had engraved stones. Oristes, in the tragedies, is also recognised as the son of Agamemnon by his engraved ring; and Mnesarchos, the father of Pythagoras, who lived about 700 B.C., was an engraver of gems. The earliest instance of an engraved gem is the emerald ring of Polycrates, set in gold or engraved by Theodorus of

Samos about 740 B.C.; while the laws of Solon against counterfeiting signets show that they may have been in early use. At the period of the

Persian war they were by no means uncommon. Later, the writings of the Platonists and Stoics constantly allude to gems, and the flute-player Isonnia, 437 B.C., purchased an emerald engraved with a figure of Amymon. Still later, the poet Esopias instances the extravagant prices given by the Cyrenians for engraved stones in rings. Yet it is doubtful if any real Greek intagli earlier than the war of Peloponnesus can be identified,

Greek Sard, with Indian Bacchus.

those hitherto cited in low relief, enclosed in a guilloche or engraved border, and of a hard and stiff style of art, having been probably cut from the bases of scarabs of Etruscan work. At a later period, their use was universal, and the names of celebrated engravers, such as Pyrgoteles and Apollonides, are known, the first named having the privilege of engraving the portrait of the monarch, Alexander the Great. Ptolemy V., presented as a most precious gift his portrait engraved on an emerald to Lucullus; and Cleopatra had a gem with Bacchus. The style of engraving of this age is fine and noble, the hair indicated by fine wavy lines; the subjects are generally heroic, but busts and portraits of divine, regal, and historical personages appear. Sard, amethyst, and jacintha were in use.

Contemporaneous with the Greek school, if not earlier, was the Etruscan, consisting of scarabs

Etruscan Scarabs: Centaur and Deer.

entirely carved out of sard, carnelian, agate, with engraving often of exquisite work, but generally harsh, and sometimes of severe style, with subjects derived from the earliest Hellenic myths, and occasional inscriptions in the Etruscan language, the names of the personages represented, seldom more than one figure appearing on the gem. The subject is surrounded with a guilloche or engraved border, and the scarabs were pierced through their long axis, to act as rings or to wear as other objects of attire. Similar scarabs, but of green jasper, and of Phœnician workmanship, have been found in Sardinia. These gems probably were made from the beginning to the middle of the 3d c. B.C., when Etruria fell into the power of the Romans, who derived their engraved stones from the Greek successors of Alexander, as engraved rings, with their subjects, are mentioned at the close of the republic, the device of Scipio Africanus being a head of Scyphax; that of Sylla, the submission of Jugurtha; of Pompey, a lion carrying a sword; and of Cæsar, Venus armed with a dart. So great had the passion for these charming little works of art increased, that Scæurus, the step-son of Sylla, had even a collection of gems, *dactylotheca*. Pompey sent the collection of Mithridates as an offering to the Capitol, and Cæsar, to outvie his great competitor, presented six such collections to the shrine of Venus Genetrix; and Marcellus another to the cella of the Palatine Apollo. At the commencement of the Empire, the portraits follow the costume and art of the period; the hair is expressed by broad

strokes, the compositions rarely contain more than two figures. Artists of great merit, as Dioscorides, Apollonides, and Chronios flourished at this age.

The names of the artists who engraved the gems, and of the proprietors, are occasionally found upon them. The devices were various: Augustus had first a sphinx, then his portrait engraved by Dioscorides; Nero, Apollo and the Muses; Galba used first a dog, subsequently the head of Augustus. After the Antonines, indeed, the art rapidly declined, and portraits after Severus are rare, although even that of Maximus is said to occur. Sard Portrait of Caligula.

At the middle period of the Empire, the work is exceedingly rude, often merely scratched out by a diamond point in carnelians, jaspers, and garnets. Some works, indeed, of the later or Byzantine period exist, but they are of poor merit and execution, and the subjects are taken from Christian subjects. The gems of this later period are sometimes square, generally, however, the long or convex oval. The *camei*, or gems in relief, the ancient *ectypa sculptura*, appear at the period of the Roman Empire. This term *camei*, of uncertain origin, is applied to engravings on stones of two or more layers, such as the onyx or sardonyx, and nuxolo, and is different from the relief-gems cut out of stones of one colour. Ancient *camei*, indeed, are of the greatest rarity, and are not older than the imperial days of Rome. The smaller ones were used for rings; the larger, which are often perforated, are supposed to have been worn in the armour or dress, *phaleræ*. They were worked out with the diamond point; chiseled, so to say, out of the stone; and have, when examined, a rough appearance. The most remarkable ancient *camei* known are those of the Vienna collection, supposed to represent the apothecæ of Augustus, on which are Augustus, Jupiter, and Rome enthroned, the Earth, Ocean, Abundance, Germanicus, Victory, a triumphal car, Tiberius, and German captives; another, in the same collection, with Ptolemy II. and Arsinoë, the great *camei* in the Bibliothèque at Paris, representing the apothecæ of Augustus; another in the collection of the Netherlands; and a fourth in the Vatican; a *cameo* at St Petersburg, one foot long, and another, eight and a half inches wide by six inches high, in the Marlborough collection, with the heads of Didius Julian and Manlia Scantilla. At a later period, the art had considerably declined, and the Christians of the later days of the Empire were content with engraving inscriptions on *camei*. These gems were principally worn as objects of attire, and Helio-gabalus is said to have placed even intagli in his shoes. The names of artists are rarely found upon *camei*; a celebrated one of the Marlborough collection, indeed, has the name of Tryphon, but there is considerable doubt about the authenticity of the inscription.

The subjects of ancient gems embrace the whole circle of ancient art, and follow the laws of its development, animal forms being succeeded by those of deities and subjects derived from the battles of Greeks and Amazons and Centaurs, the exploits of Hercules, and other heroes; then by scenes from tragedies and later myths; and, finally, by portraits, historical representations, and allegories. The inscriptions consist of the names of deities, heroes, and subjects; dedications to deities; the names of artists, sometimes in the genitive case, but often accompanied with the verb *opus*,
645

'was making' (the affected imperfect used after the time of Alexander the Great); addresses to individuals; gnomic or other sayings, indicating that the gems are amulets against demons, thieves, and various evils; or charms for procuring love; the names of the possessors, and sometimes addresses, occasionally even distichs of poetry, and various mottoes. These inscriptions were often added by subsequent possessors, and are not of the age of the gem itself. The number of artists, although very considerable, does not exceed 100 authentic names; and the true names are supposed to be distinguished from false ones by being placed at the side of the composition in very small letters terminating in dots; but even these have been successfully imitated by modern artists, and the greatest criticism and learning have been displayed to detect real ancient names by their orthography and palæography. The number of false antique stones produced by eminent engravers since the revival of the arts, has rendered the diagnosis of gems so difficult, that no branch of archæology requires greater judgment. All gems of high artistic merit and great finish are suspected, especially those with groups of many figures, regular edges, and polished faces, or too great a polish in the deep parts. Coarser imitations have been produced by backing pastes or coloured glass (see GEMS, IMITATION) with stones, and mounting them in rings, so as to pass for a gem. The appearance of wear and friction has been produced by introducing them for awhile into the gizzards of turkeys, or in pierced boxes plunged in the beds of rivers. The judgment upon gems can be, however, only matured by a careful study and familiarity with all branches of ancient art. The coarser imitations of pastes, the tongue, the file, and the graver will detect; but old gems re-engraved, or new compositions invented, require the most careful survey. The place or circumstance of discovery is only a feeble guarantee against deception, the commerce in false antiques being successfully plied upon the unwary even in the far East.

The chief implement used by the ancient engravers appears to have been made by splitting diamonds into splints (*adamantis crustæ*) by a heavy hammer, and then fixing these points like glaziers' diamonds into iron instruments, with which the work was executed by the hand (*ferra retusa*). The drill, *terebra*, was also extensively used for hollowing out the deeper and larger parts of the work, and emery powder, the *smaris* or Naxian stone, for polishing. The so-called wheel, a minute disk of copper, secured to the end of a spindle, and moistened with emery powder or diamond dust, and driven by a lathe, does not appear to have come into use till the Byzantine epoch. It has been conjectured that the artist used lenses of some kind, or globes filled with water, to execute his minute work; but the ancient, like the modern engraver, rather felt than saw his way. All these processes were not employed by the same artist, for besides the engraver (*sculptor cavarius, dactyliographus*), there was a polisher (*politor*), not to mention arrangers (*compositores gemmarum*), and merchants (*gemmarii, mangones gemmarum*) who drove a flourishing trade in emeralds and pearls and engraved stones in the days of Horace.

The general fall of the arts at the period of the Byzantine Empire, seems to have been accompanied by the decline of the art of engraving on gems; and the Merovingian and Carolingian monarchs were obliged to use antique gems, instead of those engraved by the artists of their day. Rock-crystals, however, were engraved in a Byzantine style of art, with sacred subjects, in the 9th c.; but

the art was all but lost till the rise of Lorenzo de Medici, when Giovanni delle Corniole at Florence, and Domenico dei Camei at Milan, worked under his patronage. A subsequent school of gem-engravers originated with Pietro Maria de Pescia, who worked for Leo X.; the chief representatives of the school are Michelino, Matteo de Benedetti, the celebrated painters Francia, M. A. Moretti, Caradosso of Milan, Severo of Ravenna, Leonardo da Vinci, J. Tagliacarne, Bernardi of Castel Bolognese, who died 1555, celebrated for a Tityus copied from M. Angelo. These were succeeded by Matteo del Nassaro of Verona, who worked for Francis I., and produced a crucifixion on heliotrope, so that the red spots seemed drops of blood issuing from the wounds of Christ; Caraglio, who flourished in Poland in 1569; Valerio dei Belli, who chiefly employed rock-crystal; Marmitta, Domenico di Polo, Nanni, Anichini of Ferrara, and Alessandro Cesari, celebrated for a cameo head of Phocion; Dei Rossi, a Milanese, engraved the largest cameo of modern times; Jacomo da Trezzo, celebrated for his portrait, is said to have been the first to engrave on the diamond in 1564—an honour disputed, however, by Birago, another Milanese, both artists having been in the service of Philip II. of Spain, who made a portrait of Don Carlos and the arms of Spain on this gem.

The art, which had declined at the close of the 16th c. in Italy, flourished in the 17th c. in Germany under Rudolph II., for whom Lehmann engraved at Vienna; and in France, where Coldore worked for Henri IV. and Louis XIII. In the 17th c., Sirletti, who died at Rome in 1737, excelled in portraits, and copied antique statues with great excellence. The two Costanzi are celebrated in 1790, one for the head of Nero on a diamond. Rega of Naples is said to have come nearest to the antique. Natter of Nuremberg, who died in 1763, is celebrated for his intagli; Guay and Barrier were celebrated in the French school; and the English produced Reisen, who died 1725; Claus, who died 1739; Smart, celebrated for the rapidity of his works; and his pupil Seaton, a Scotchman, who engraved portraits of the great men of his day. The greatest artist of the age, however, was Natter, who died in 1791. Of the subsequent Italian school, Ghinghi, Girometti, Cerbara, Bernini, and Putenati are much praised. The 19th c. produced many good English engravers, as Marchant, Burch, Wray, and Tassie; while Pistrucci, celebrated for his charming cameo, Weigall, and Saulini, who made intagli, complete the list of modern gem-engravers.

With respect to ancient gems in the dark and middle ages, they were preserved in shrines, chasses, and other ecclesiastical vessels in which they were set, the passion for collecting them as works of art having commenced with Lorenzo de Medici, who formed the Florentine collection, and had his name incised on his gems. The large camei of the European collections, however, appear to have been brought by the Crusaders from the East. The French collection dates from Charles IX., and was augmented by the successive kings of France; it is very rich in gems of all kinds; that of Berlin containing the united cabinets of the Elector of Brandenburg and the Markgraf of Anspach, collected by Stosch, consists of nearly 5000 stones. The Vienna collection, far less numerous, is remarkable for its large camei. In England, the collector of the British Museum, collected originally by Townley, Hamilton, Payne, Knight, and Cracherode, consists of about 500 stones, some of great beauty and merit, but is very poor in camei. The private collection of the Duke of Devonshire, formed in the last half century, comprises upwards of 500 intagli

and camei, including some of the finest known. The Marlborough, still more numerous, comprises many fine camei and intagli, and numerous works of the renaissance. The Pulzky collection, now in Italy, contains many rare and choice intagli. A celebrated collection, the Poniatowsky, formed upon the base of the old collection of Stanislaus, last king of Poland, was so filled with forgeries by its last possessor, executed by Roman artists with inscriptions by Diez, that it entirely lost its value on dispersion. The Hertz collection, the last great one sold, was remarkably rich in fine Etruscan scarabæi and other intagli. There are probably about 10,000 gems reputed to be antique. Yet these are only a mere instalment of those formerly existing. The immense value placed by the ancients on their gems, may be seen by the scabbard of Mithridates, valued at 400 talents, or £7572; the pearl given by Julius Cæsar to Servilia, worth £4800; that swallowed by Cleopatra, valued at £5000; and the pearls and emeralds worn by Lollia Paulina, wife of Caligula, valued at £320,000—all the spoils of provinces and the heirlooms of her family. These, indeed, were probably not engraved, but in modern times great sums have been paid to celebrated engravers, as much as £800 for one cameo.

Although the acquisition of gems is too costly for private individuals, impressions in glass, called pastes (see GLASS), in sulphur, gutta percha, or plaster of Paris, can be easily obtained, and they answer almost all the purposes of study. Some ancient impressions in terra cotta, indeed, exist, and the poorer classes of Greece and Rome were content with glass pastes. The value of antique gems, owing to the great difficulty of discerning those really so, has considerably declined in this country, and even their authority is very cautiously cited by archaeologists. The principal writers of antiquity who treated of gems are, Onomacritus or the Pseudo-Orpheus, Dionysius Periegetes, Theophrastus, and Pliny, whose chapter is compiled from antecedent Greek and Roman authors. Isidorus, 630 A.D., gives an account of the principal stones; so do Psellus and Marbodius in the 11th c.; Mariette, *Pierres Gravées* (4to, Paris, 1750); Raspe, *Catalogue des Empruntes des Pierres Gravées* (4to, Lond. 1757); Millin, *Introduction à l'Étude des Pierres Gravées* (12mo, Paris, 1796); Krause, *Pyropoteles* (8vo, Halle, 1856); Koehler, *Ueber die Geschnitene Steine* (8vo, St Petersburg. 1851); King, *Antique Gems* (8vo, Lond. 1860).

GEMS, ARTIFICIAL. Ever since the chemical composition of our most valued gems—the diamond, ruby, opal, &c.—has been known, attempts have been made, with more or less success, to reconstruct them in the laboratory by the influence of intense heat, electrical action, &c. Amongst the most successful workers in this field, we may mention Ebelmen,* Despretz, Sainte-Claire Déville, and Becquerel.

There are at present no reasons for believing that diamonds of any appreciable size will be formed artificially; Despretz has, however, succeeded, by intense voltaic action, in obtaining minute, dark-coloured crystals of carbon.

Boron, which was discovered simultaneously in 1807 by Davy in England, and by Gay-Lussac and Thénard in France, was first exhibited in a crystallised form by Wöhler and Sainte-Claire Déville. They have not, however, succeeded in obtaining perfectly pure crystals. The different tints which they exhibit are due to the presence of small quan-

tities of carbon in a crystalline state (the same condition in which it occurs in the diamond) and of aluminium. It is not impossible that in the discovery of crystallised boron, we may have advanced a step towards the artificial production of the diamond. The boron crystals possess a brilliancy, hardness, and refractive power scarcely inferior to those of the diamond.

Sainte-Claire Déville and Caron have published a very important Memoir in the *Comptes Rendus* (1858, vol. xli.), in which they describe various processes by which they have succeeded in obtaining small crystals of white and green corundum, rubies, sapphires, &c. By the action of the vapours of fluoride of aluminium and boracic acid on one another, they obtained crystallised alumina (corundum) in large, but thin crystals, some of which were about $\frac{1}{4}$ of an inch in length, and which in their hardness, and in all their optical and crystallographic properties, resembled natural corundum. When a little fluoride of chromium was added, a similar process yielded violet-red rubies of a perfectly natural tint; with rather more fluoride of chromium, blue sapphires were yielded; and with still more of this ingredient, green corundum was obtained, presenting the natural tint of the variety known as ouvaroffite. A mixture of equal equivalents of the fluorides of aluminium and glucinum, when similarly acted on by boracic acid, yielded crystals of chrysoberyl or cynophane, which, although very minute, were perfect in their form, and in all respects resembled the natural crystals. The action of fluoride of silicium on zirconia yields small crystals of zircon or hyacinth ($Zr_2O_3 \cdot SiO_2$); and by the action of silicic acid on a mixture of the fluorides of aluminium and glucinum, hexagonal plates of extreme hardness were obtained, which in some respects resembled emerald (which they were attempting to form), but were not identical in composition with that gem.

The latest researches on this subject are those of Becquerel in the *Comptes Rendus* (1861, vol. liii. p. 1196). After having for many years tried to obtain gems from solutions of silicates, and by feeble electric currents, he now uses intense currents, with high tension, and in this way has succeeded in obtaining opals, &c.

GEMS, IMITATION, OR PASTES, *Pierres Précieuses Artificielles*. French imitations of the precious stones, are made of glass specially prepared. It differs from ordinary glass in its greater density; at the same time it is made with the greatest possible amount of transparency and purity. Its composition, generally, may be said to be silica of very pure quality, probably quartz crystals, potash, and oxide of lead; but the exact proportions are varied almost by every maker, and each has a secret ingredient or two to add.

The colours employed are usually the same as those used for colouring ordinary ornamental glass, but upon their careful admixture, and upon the skilful cutting to represent the crystalline form of the real gem, the success of the manufacture chiefly depends. By some persons, the cutting is carried to such a marvellous perfection, that their work would deceive the eye of most ordinary judges, when well set and *foiled*, or backed with silver or tinfoil. See FOIL.

The glass used for artificial gems is very generally called *strass*, from the name of a German who claimed the invention. But if we seek the real inventor of factitious gems, we must go far beyond the time of Strass, for we find Pliny describing under the name of *gemmæ vitreæ*, certain imitations of precious stones which were known in his time, some of which were certainly made of coloured

* Ebelmen's memoirs on this department of chemistry are contained in the first volume of Salvétat's *Recueil des Travaux Scientifiques de M. Ebelmen*. Paris, 1855.

glass, and others by ingeniously cementing together layers of variously coloured transparent stones. And Seneca (Epist. ix.) mentions that one Democritus had invented a process for imitating emeralds by giving a green colour to rock-crystal. Other allusions are plentifully scattered through the works of classical authors; and ancient artificial gems themselves exist, two especially famous being imitations of a chrysolite and an emerald, amongst the Roman antiquities in the Museum Victorium at Rome.

The manufacture of factitious gems is chiefly carried on in Switzerland, and like the polishing of diamonds in Holland, is engrossed by a small community in the French commune of Septmoncel, on the Jura Alps, 16 miles from Geneva. Upwards of a hundred artisans are there employed in this manufacture, and they make almost enough to supply the whole world. Much common coloured glass is cut up in this country for the purpose of making the gilt-toy jewellery, but the writer believes that a small manufacturer of the name of Weston, in Birmingham, is the only person who attempts fine imitations of precious stones with coloured strass. The following are a few known formulas for imitating gems: *Amethyst*—Strass, 500 parts; oxide of manganese, 3 parts; and oxide of cobalt, 2 parts. *Diamond*—Perfectly pure rock-crystal, 1600 parts; biborate of soda, 560 parts; very pure carbonate of lead, 3200 parts; oxide of manganese, 1 part. A glass, consisting only of the oxide of tin, fused, is used for the so-called Parisian diamonds; they are the nearest in brilliancy to the real gem when newly made, but they soon lose their brilliancy. *Emerald*—Strass, 7000 parts; carbonate of copper, 65 parts; glass of antimony, 7 parts. *Garnet, Oriental*—Strass, 1200 parts; glass of antimony, 580 parts; Purple of Cassius, 3 parts; binoxide of manganese, 3 parts. *Ruby*—Strass, 45 parts; binoxide of manganese, 1 part. *Sapphire*—Strass, 3600 parts; oxide of cobalt, 50 parts; oxide of manganese, 11 parts. *Topaz*—Strass, 1050 parts; glass of antimony, 44 parts; Purple of Cassius, 1 part.

GEMS-BOC (*Antelope Oryx*, or *Oryx Gazella*), a species of antelope, described by some naturalists as the *Oryx*, but which, being a native of South Africa only, cannot be the *Oryx* (q. v.) of the ancients,

the ridge of the back; large pointed ears; and almost perfectly straight horns, fully two feet long, in the plane of the forehead, little diverging, and obscurely ringed at the base. The colours are harshly contrasted, dark rusty gray above, and white on the under parts, separated by a broad dark brown or black band; the head white, with black transverse bands; the thighs black, and the legs white. The hoofs are remarkably long, adapted to the rocky mountainous districts which the animal frequents. The G.-B. makes such use of its horns as sometimes even to beat off the lion. It inhabits districts free from wood, and is generally found in pairs or in very small herds.

GEMSHORN, a well-known organ-stop in German organs, the pipes of which are made of tin, and are conically shaped, being much narrower at the open end; while at the mouth, at the broad end, there are ears on each to regulate the tuning. It has a peculiarly pleasant tone, of a different character from either an open cylinder pipe or a stopped pipe. The pitch of the gemshorn is generally 8 feet tone, sometimes it is 4 feet, and in the pedal organ 16 feet.

GENDARMES (*Men-at-arms*), originally, and up to the time of the first French revolution, the most distinguished cavalry corps in the service of the Bourbon kings, to whom they formed a sort of body-guard. Under existing arrangements, the gendarmes constitute a military police, and comprise both cavalry and infantry. The force consists principally of soldiers taken from the army, generally on account of intelligence and good conduct. The men receive much higher pay than the rest of the army, of which, however, the corps is a part, and they are liable in cases of emergency to be sent on active service. The gendarmes now amount to about 25,000 men, and are intrusted with the execution of many of the most delicate details of government.

GENDER (Fr. *gendre*, from Lat. *genus*, *generis*, race, kind), in Grammar, is a distinction among words depending upon sex. Names applied to the male sex are said to be of the masculine gender, as *man*, *poet*; those applied to the female sex, feminine, as *woman*, *poetess*; words that are neither masculine nor feminine are, as it was expressed in Latin, *neutrius generis*, 'of neither gender;' and from this phrase grammarians have come to speak, somewhat incorrectly, of this class of words as being 'of the neuter gender,' and hence to reckon three genders. In English, the distinction of gender in nouns is chiefly marked in the pronouns substituted for them—*he*, *she*, *it*. Gender, strictly speaking, is applicable only to living beings distinguishable as male and female; but by the figure of speech called Personification (q. v.), inanimate objects are often spoken of as *he* and *she*. In the infancy of language, however, when every word was what we should now call a metaphor—when every thing that moved or was seen to produce any effect, was conceived as actuated by a conscious will, like that which the spectator felt within himself—every prominent or interesting object in the universe would be invested with one or the other sex, according to the analogy it suggested. In Latin, accordingly, *gladius*, a sword, was considered masculine; *navis*, a ship, as feminine; and *pomum*, a fruit or apple, was thought of as without sex. Similarly, in Sanscrit and Greek, the greater part of inanimate objects are either masculine or feminine, the others being neuter. In Hebrew, everything is either masculine or feminine, there being no neuter; and this is the case in the modern languages derived from the Latin, viz., Italian, French, Spanish, and Portuguese—everything

Gems-boo (*Antelope Oryx*).

although it is certainly a nearly allied species. It is a heavy, stout animal, about the size of a stag, with rough reversed hair on the neck and along

is either a *he* or a *she*. German resembles the classic languages in making some inanimate objects masculine, some feminine, and others neuter. Thus at table, a man must speak of the spoon (*der löffel*) as 'he,' of the fork (*die gabel*) as 'she,' and of the knife (*das messer*) as 'it.' English—in this more rational than any of its congeners—has banished the spurious distinctions of gender that encumbered the Anglo-Saxon like the other Teutonic tongues, and attributes sex only to living beings.

In the highly inflected languages, there are certain terminations distinctive of the different genders. It is probable, indeed, that originally every noun, substantive, or adjective, had a suffix indicative of the sex, real or imaginary, of the object designated, although, like other inflexions (q. v.), these suffixes of gender were in process of time mutilated beyond recognition, or in many cases altogether worn off. The terminations most characteristic of the three genders in Latin are *mas. us*; *fem. a*; *neut. um*; corresponding to the Greek *os, ē, on*. In a great majority of the adjectives in both those languages, the genders are thus marked. In English, the gender of a noun affects only the personal pronoun substituted for it; in most other languages, the adjectives (including the articles) have different forms for the several genders—a useless complication, in the case of modern languages at least. See **ADJECTIVE**.

Of the terminations distinctive of gender observable in modern English, some are purely Latin, as in *executor, executrix*; the feminine *-ess*, as in *countess*, is borrowed from the French, and is also of classical origin. The prevalent feminine termination in German is *-inn*, as in *tänzerinn*, a female dancer (Fr. *danseuse*); of this there are two instances in English, in the provincial *carlin*, the fem. of *carl*, and *vixen* = Ger. *fuchsin*, a female fox. This affix was already in use in Latin, as in *regina*, a queen, *reg(e)*, a king; and in this form it is used in Europe generally to feminise proper names; e. g., *Georgina, Wilhelmina, Caroline*.

In such pairs as *son—daughter*; *man—maid*; *horse—mare*; *cock—hen*; there is no etymological relation between the words; they are from distinct roots. But with regard to *hen*, e. g., the Anglo-Saxon had the two forms, *han* for the male, and *hen* for the female; and *mare* was originally applicable to both sexes, as *horse* still is (Fr. *maréchal*, originally an officer who had charge of the horses). The oldest known form of the Teutonic speech, the Gothic, had the two words, *magus*, son, and *magatha*, daughter, both from the root *mag*, to beget, or to make. *Magatha* has become in Ger. *magd*, in Eng. *maid*; *magus* has been lost in the Teutonic tongues, but it is represented by the Celtic *mac* (son), evidently from the same root. *King, queen*, were in Sans. *ganika*, father, and *goni*, mother, both from the root *gan*, to generate, produce. The masculine form appears in Old Ger. as *chunig*, in modern Ger. *könig*, in Eng. *king*; the feminine became the Greek *gynē*, a woman, as well as the Saxon *cwen*, Sw. *quinna*, Old Eng. *quene* or *quean*, applied to a woman generally, and the modern, *queen*, the chief woman of the land.

GENEALOGY (Lat. and Gr. *genealogia*; from Gr. *genos*, race, and *logos*, discourse) is the name applied to the science of the origin, sequence, and affinities of families. Although in itself it is not of sufficient importance to rank as an independent science, yet in so far as it has to do with remarkable and influential families, it forms a very important part of history. It naturally divides itself into two parts, *theoretical* and *practical*. The former embraces the principles on which the

science of genealogy is based, while the latter is occupied with tracing the course of particular families themselves. To render perceptible to the senses the descent and relationship of individuals, genealogical tables are made use of, whose arrangement depends on the special purpose for which they are constructed. Usually, however, such tables begin with the earliest ancestor (Ger. *stammvater*) of a family, from whom all the known members of both sexes are traced in the order of descent. The importance of this branch of human knowledge, however, is perhaps less obvious in a scientific than in a legal aspect, where it is concerned about the various claims or pretensions of persons based on real or alleged relationship, more especially in regard to rights of succession. The earliest traces of genealogy are to be found in the ancestral catalogues of the heroes of the old world. Among the Hebrews, there were parties specially appointed to draw up genealogical tables. The progress of civilisation in states, and in particular the institution of corporations and guilds in the towns, afforded a wider scope for genealogy. But the absence of criticism, and the desire to flatter the great, were the causes of introducing—especially after the 14th c.—the most ridiculous fables into genealogy. Ancestors were fabricated in the most impudently false manner, and families carried back in an unbroken line, not only to the age of Charlemagne, but even, in many cases, to the heroes of the Trojan war. The fact, however, is, that scarcely any family, however distinguished, can trace its ancestors even to the middle of the 11th c. Among the earlier works on genealogy are Ruxner's *Turnierbuch* (Simmern, 1527) and the genealogical tables of Reusner and Hennings, about the end of the 16th c., but these are not conceived in a historical spirit. A more luminous treatment of the subject was initiated in France by Duchesne, St Marthe, Hozier, Chifflet, Lancelot le Blond, &c., and in England by Dugdale. Rittershusius of Altdorf (died 1670) and Spener of Wittenberg (died 1730) were the first in Germany to base genealogy on documentary evidence. The path entered on by them has been prosecuted by König, Von Imhof, and especially by Hübner in his *Genealogischen Tabellen* (4 vols., Leip. 1725—1733; new edit., 1737—1766), to which Lenz added *Erläuterungen* (Elucidations, Leip. 1756), and Sophia queen of Denmark, *Supplement-tafeln* (Kopenh. 1822—1824). Gatterer, in his *Abriß der Genealogie* (88tt. 1788), founded the scientific treatment of the subject, in which he was followed by Putter in his *Tabula Genealogica*, by Koch in his *Tables Généalogiques des Maisons Souveraines d'Europe* (Ger. Berlin, 1808), and by Voigtel in his *Genealogischen Tabellen* (1810).

In Great Britain, the chief printed collections of genealogical information are the *Peerages, Baronages, Baronetages, and County Histories*. The chief manuscript sources are the public records, heraldic registers, and the parish registers of births, marriages, and deaths.

GENERAL (of religious order), in the Roman Catholic Church, the supreme head, under the pope, of the aggregated communities throughout Christendom belonging to a religious order. The governing authorities of the monastic orders in the Roman Catholic Church may be arranged in three classes: (1.) The superiors of individual convents or communities, called in different orders by the various names of abbot, prior, rector, guardian, &c.; (2.) The provincials, who have authority over all the convents of an entire province—the provinces, in the monastic sense of the word, being usually coincident as to local limits with the several kingdoms in which

GENERAL AGENT—GENERAL OFFICER.

the order is established; (3.) The general to whom not only each member of the order, but all the various officials of every rank, are absolutely subject. The general is usually elected commonly by the general chapter of the order, which, in the majority of orders, consists properly of the provincials; with whom, however, are commonly associated the heads of the more important monasteries, as also the superiors of certain subdivisions of provinces. The office of general in most orders is held for three years. In that of the Jesuits it is for life; but in all; the election of the general chapter must be confirmed by the pope. In most orders, too, there is assigned to the general a consultant (*admonitor*) or associate (*socius*), who, however, is only entitled to advise, but has no authority to control the superior. The general also is supposed to consult with and to receive reports from the various local superiors. He sends, if necessary, a visitor to inquire into particular abuses, or to report upon such controversies as may arise, and he holds a general chapter of the order at stated times, which differ according to the usage of the several orders. The general is exempt from episcopal jurisdiction, being subject to the immediate jurisdiction of the pope himself. He resides in Rome, where he enjoys certain privileges, the most important of which is the right to sit and vote with the bishops in a general council of the church.

GENERAL COUNCIL. See **PRIVY COUNCIL.**

GENERAL DEMURRER, in English pleading, was a Demurrer (q. v.) without shewing special cause. Where the objection to the pleading was for want of form, a special demurrer was necessary; but where the defect was in substance, a general demurrer was sufficient. By the Common Law Procedure Act (1852), special demurrers have been abolished, and the distinction has ceased to exist.

GENERAL ISSUE, in English pleading, is the form in which the defendant traverses or meets with a simple denial the whole allegations, or the principal fact on which the plaintiff relies in his declaration. Thus, in actions founded on wrongs, the general issue is 'Not Guilty'; in actions of debt, that the defendant never was indebted; in actions on a deed or bond, *non est factum*, i. e., that it is not the deed of the defendant. Under this issue, the defendant may prove that he never executed the deed; but not that it is bad in point of law. In *criminal proceedings*, the general issue is 'Not Guilty,' by which plea, without further form, every person, not having the privilege of peerage, upon being arraigned upon any indictment for treason, felony, or piracy, is deemed to have put himself upon the country for trial. Where a prisoner refuses to plead, a plea of Not Guilty may be entered for him, 7 and 8 Geo. IV. c. 28. Under the plea of Not Guilty, the prisoner is entitled to give in evidence not only everything which negatives the charge, but also all matter of excuse or justification.

GENERAL LIEN, in English Law, is the right which a party has to retain a chattel as security for the payment, not only of the particular article, but of any balance that may be due on general account in the same line of business. General liens do not exist at common law, but depend upon agreement, either express or implied, or upon the usage of trade. Thus, attorneys have a lien for the balance of their accounts over the papers of their clients. Bankers, factors, warehousemen, and others, have

also a lien for the amount due to them on the general balance of their accounts. But it has been held that fullers are not entitled to this privilege, *Rose v. Hart*, 8 Taunt. 499. The right of wharfingers also is not clear in all cases, *Holderness v. Collinson*, 7 Barn. and Cres. 212. In regard to carriers, there has been much dispute whether, by the usage of trade, they have a general lien over goods intrusted to them; but the prevailing opinion appears to be that they have. The master of a ship has no lien on the vessel or her freight for his disbursements on her account; but now he has the same lien for his wages as a seaman has; 17 and 18 Vict. c. 104, s. 191. By 6 Geo. IV. c. 94, it is provided that any person in whose name goods are shipped shall be deemed to be the owner so far as to entitle the consignee to a lien for any advances made for the use of such persons, provided the consignees had no notice when the advance was made that they were not the true owners. As a lien rests upon the right to retain possession, it is lost by abandonment of the possession of the goods.

In Scotland a similar right exists, under the title of Retention (q. v.). See also **LIEN**, and **HYPOTHEC.**

GENERAL OFFICER is an officer of the general staff of an army to whom is intrusted the command of a body of men, not less in strength than a Brigade (q. v.). In an army of very large proportions, the normal sequence of command would be the following: the general commanding-in-chief, generalissimo, or field-marshal, would command the whole force; the generals would have separate *corps-d'armée*; the lieutenant-generals, wings of those *corps-d'armée*; the major-generals, divisions in the wings; and brigadier-generals, brigades in the divisions. In practice, however, an army is rarely large enough to allow of this exact scheme of a military hierarchy being strictly carried out.

In the British service, colonels become major-generals (except in cases of selection for very distinguished service) in order of seniority, provided each has served on full pay for a certain number of years; promotion to be lieutenant-generals and generals follows in exact order of seniority. From the last, promotion to the exceptional rank of field-marshal is conferred in rare instances by the special favour of the sovereign, who represents in person the sole command and possesses the patronage of all the land forces. In addition to the colonels who become effective generals, officers who have retired on half-pay at earlier periods of their careers rise by seniority to the rank of general officers; but they continue, notwithstanding, to receive only the half-pay of the rank in which they retired. With regard to remuneration, general officers hold 164 honorary colonelcies of regiments, worth, with few exceptions, £1000 each per annum, and the remainder receive *unattached* pay of £600 a year, if they have been in the guards; £1, 6s. 3d. a day, if in the artillery or engineers; and £1, 5s. a day, if previously in the line. This pay is received during non-activity, but when employed actively a general receives, in addition, £5, 13s. 9d. a day; a lieutenant-general, £3, 15s. 10d.; and a major-general, £1, 17s. 11d., besides various allowances. The only generals' commands in the British service are, during peace, the commands-in-chief of the army generally and of the force in India. According to the estimates for 1862—1863, there are 8 lieutenant-generals, 29 major-generals, and 10 brigadier-generals employed actively, exclusive of the numbers serving with the army in India. The last-named rank is only a temporary one in the English service, conferred very commonly on the senior regimental officer of the corps composing the brigade: during duty as brigadier he receives £1, 8s. 6d. a day in addition to

regimental or other pay. *Captain-general* is a rank very rarely conferred by the sovereign, who holds it *ex officio*. There has been no captain-general, other than the sovereign, during the present century.

GENERAL SHIP, is a ship which has been advertised by the owners to take goods from a particular port at a particular time, and which is not under any special contract to particular merchants. The owners, in this case, engage separately with each merchant who applies to them to convey his goods to the ship's destination. The contract between the owners, or the master acting in their behalf, and the proprietors of the goods, may in the case of general ship be established by parole evidence, and, indeed, there is rarely any other writing on the subject beyond the advertisement and the bill of lading. In general ship the master being intrusted by the owners with full power to contract for and take in goods, no agreement for freight which any one may have made with the owners, independently of him, will be effectual to secure room in the vessel. All such agreements must be intimated to the master, or those acting for him on board, before he has engaged freight for the whole vessel. By such intimation, a preference will be secured over the merchant who brings his goods to the ship's side on chance. If the owners of a general ship have advertised her as bound, for a particular port, they must give specific notice to every person who may ship goods on board, of any alteration in her destination, and they will be liable for the consequences of neglecting to do so. *Bell's Com.* i. 433, Shaw's edition; Abbot on *Shipping*, p. 233.

GENERAL VERDICT. See **VERDICT**, **JURY**.

GENERALISATION. Our experience of the world leads us to recognise not only great variety, but also numerous instances of agreement in the midst of the variety. We do not call the continuance of the same fact an agreement; it is only when, amid difference of accompaniment, we recognise a common feature, that our attention is awakened, and our mind interested. Sometimes the common feature in a number of varying objects is obvious and universally noticed; as when we identify the round form amidst all disparities of size, colour, and substance. At other times, the resemblance is so obscured by the amount of difference, that it has lain for ages unperceived; the fall of a stone was never suspected, before the time of Newton, to have anything in common with the motions of the moon and planets. When we see the same property or effect repeated under great variety of circumstances and adjuncts, and when we indicate by a name or otherwise that this agreement exists, we are said to mark out a *general* or generalised property, or fact; while the individual instances are termed the *particulars*, on which the other is grounded.

To understand the full meaning of generalisation, and the questions therewith connected, we must advert to the distinction between two modes of the operation. In the one, we generalise an individual or isolated property—as roundness, whiteness, weight, attraction, justice—and assign what we think the exact nature of the common feature thus singled out. A number of designations have been given to this process, according to the particular stage in the operation most specially taken into view; these are *Classification*, *General Notion*, *General Term*, *Definition*, *Abstraction*, *Concept* or *Conception*, *Idea*. They all suppose that we have a plurality of objects with agreeing properties, and that agreement has been taken notice of, and embodied in such a form, that the mind can deal with it to the neglect of the points wherein the particular things differ among

themselves. They suppose, further, that we make no affirmation beyond what is implied in the identifying of so many differing objects—namely, that they do agree in the point in question. No other matter for belief or disbelief is presented in the notion of roundness but that certain things have been compared, and have been found to agree in possessing that attribute. To attempt to form a general notion, or to mark a property not attaching to anything in nature, is a pure irrelevance and absurdity; and although by a bold stretch of imagination we might people the earth with chimerical objects, and find agreements among them, yet such generalities could not be introduced into any process of reasoning; it is presumed, that wherever a general property is specified, there are things in nature having this property in company with the others that make up the total characteristics of each.

But the other kind of generalisation introduces belief in a totally different shape. When instead of identifying a property, we identify a union or *conjunction* of distinct properties, it has to be seen not merely whether the common features are correctly rendered in the general notion, but whether the alleged coupling always takes place. Thus, when we compare the sea coasts all over the globe, we find, with some exceptions, that twice a day the sea advances and recedes on the shore: this fact we express by the general name the tides. When, however, we go further, and note everywhere the *coincidence* between the tides and the positions of the moon, and generalise that coincidence, we attain to a more complicated result. We are now called upon to believe not merely in the accurate correspondence of a general notion with the particular objects, but in the constancy of the conjunction between two distinct properties, so that the occurrence of one shall always count as evidence of the other. The different aspects of this higher operation have given rise to another series of designations, contrasting with those given above for the simpler operation; these are *Induction*, *Inductive Generalisation*, *Conjoined Properties*, *Affirmation*, *Proposition*, *Judgment*, *Law*, *Order of Nature*. These all involve truth or falsehood, inasmuch as they all pretend to give us a positive assurance that wherever we find one thing we shall find some other thing present or absent, and be enabled thereby to anticipate our individual experience of the course of nature. A general notion can often be expressed in a single word; the *noun* is the part of speech that names both particular objects and general notions. A general proposition is a complete thought, and requires a sentence for its enunciation; it involves the *verb* along with the noun. Heat is a notion, and so is Light; but when we unite the two in the affirmation that heat is the cause of light, we indicate something that is true or false, that may be proved or disproved, believed or denied.

This higher form of generalisation is treated of under **INDUCTION**. On the other and simpler form, a few further explanations are added here. In the operation of forming a general notion, the first step is something of the nature of *Classification*. We must assemble in our view a number of particular objects, being moved to bring them together by the attractive bond or association of similarity. The objects thus assembled are a class. In Natural History, for example, we bring together in the mind all the quadrupeds that we have ever had any knowledge of, and the array constitutes a class, grounded on the peculiarity of walking on all-fours. Another class is made up of the animals that fly in the air; a third, of those that live in the sea. By such successive groupings of creatures that have a kindred nature in one or more respects, we gradually

GENERALISATION.

include the whole of the animal kingdom known to us in a series of classifications, whereby method and order are introduced into the otherwise heterogeneous mass. So in plants and minerals, and all through nature. According as likenesses have been discerned in the constituent parts of the universe of things, the individuals are placed with those related to them, and a great simplification of view and extension of knowledge are the results. For it happens very frequently, that likeness in one point is accompanied with likeness in other points, so that we can couple several peculiarities together, and rise to general truths as well as general notions. When a classification has been arrived at that leads to this consequence, we put a more than ordinary value upon it; we consider that we have seized upon some fundamental and pregnant point of resemblance, something that conveys the most essential nature of the objects classified, and we are accustomed to style the group that so arises a *natural* or a *philosophical* classification. The arranging of animals according to the element they live in, as land, water, air, so very obvious to the first observers, has given place to one founded on other kinds of likeness—namely, the structure of the skeleton and the mode of bringing forth and rearing the young; it being proved that a greater number of important attributes are bound up with those characteristics than with the element that the animals inhabit. See Mill's *Logic*, book iv. chap. 7.

The forming of a class leads to the adoption of a Class Name, in other words, of a *general name*, which is a name applicable to every individual member of the class, in consequence of being understood to express no more than they all have in common. Thus we have the name 'round' to express all round objects, omitting any reference to other peculiarities that may attach to them. So the names 'bird,' 'heath,' 'salt,' are applicable alike to a vast number of individual things. When the general name has been devised, we can by means of it speak of all the particulars in one breath, on condition that we intend only to refer to the points of community.

The process called Abstraction is further implied. When we bring together, or constitute a class, in virtue of a prevailing resemblance, we are said to 'abstract' from the individuals everything else except the points of agreement. In the language of Sir W. Hamilton, we *attend* to the likeness and *abstract* the differences. The notion that we have of the common quality is termed by the same philosopher the Concept; but it has been usual to employ the phrase 'abstraction' or 'abstract idea' for the same purpose, although a perversion of the original application of that word. The common attribute of round bodies, the round figure, or form, is the concept, or the abstract idea of roundness. The precise character of this mental element or process has been much disputed in philosophy, there being three different sects that have grown up in connection with it; the Realists, Nominalists, and Conceptualists. The Realists gave an actual independent existence to the prototypes of our general notions, maintaining that apart from all circular bodies there existed in nature a circular *form*, having no other attribute soever, like a circle of Euclid bereft of the actual line required to mark the figure to the eye. The Nominalists considered that the only general thing was the common name; the Conceptualists allowed a mental existence to the generalised attributes, but no more. (Sir W. Hamilton's *Metaphysics*, vol. ii. p. 296.) The last are, no doubt, near the truth; for although we cannot, with Plato, affirm the existence in nature of 'generals' that have no embodiment in particulars

(which would be to contradict the very essence of generalisation, namely, likeness *among unlikenesses*), we must still grant to the mind the power of attending in thought to what is common, neglecting for the time the disagreements. We can think of all the consequences of the circular figure, without specially attending to the other peculiarities of any individual circle. This abstractive process is performed in different ways, according to the nature of the subject. In geometry, for example, we can draw diagrams that are little other than naked forms, although we must make them of a definite size; and in contemplating these, we are enabled to think of form without substance. We cannot use this method in Natural History; we cannot form a conception of a bird by a diagram that gives nothing but what is common to all birds. If we are reasoning upon the properties of the class, we may first call into view some one as an example, say a pigeon; from considering which, we can go so far as to note the common peculiarities of feathers, wings, bill, &c.; and when we have completed the description, we run over in our mind a number of other birds, to see that we have not mentioned points special to the pigeon. In fact, we must have within call the whole of the members of the class, if we would reason generally respecting it. After we have thus checked and corrected our generalised description, we can embody the abstract idea in a form of very wide occurrence in our general reasonings, namely, a verbal statement of the common attributes. By means of this, we may often dispense with the reference to the particulars, except to know the precise meaning of the language, which meaning is still some sort of general conception of the objects. We must have a general notion of feathers, and of the structure of the bill in birds, upon the plan above mentioned of holding in the mind some typical instance subject to correction by a comparison of all the instances coming under the genus. So that, in point of fact, no general reasoning has ever been invented to supersede totally this reference to the particulars; the formal reasonings of mathematics require us still to have in the mind concrete quantity, or one thing as equal to, greater than, or less than, another.

These remarks lead us to the nature of Definition, which is one of the important designations growing out of the operation of generalising. To define, is to limit, settle, and specify the exact compass of the properties common to a class. Usually this is done by means of language; but in reality it is, and must be done, by a reference, direct or remote, to the particulars themselves. This reference frequently has the appearance of being dispensed with. The reason is that many general notions are compounded of others, and we can understand the composite notion from its components, without going further; that is, without producing particulars. Thus, a circle in the abstract might be made intelligible by pointing to a number of concrete circles, such as are drawn in Euclid; we should then have to impress on our minds a sufficient number of these to prevent us from ever associating with the general idea any one size, or any one colour of the outline (which must be drawn in black, red, blue, or some other colour). No one circle is really the general notion; this must be nothing less than a multitude of actual circles, which the mind apprehends by turns, so as to be sure of never affirming any attribute as common that is in fact peculiar to one or a few. But the concept, circle, can be got at in another way. If we determine first what is called a 'point' in space, and a 'line' proceeding from that point, and made to revolve around it, the other extremity of the revolving line will mark a course which is a circle.

Here, if we possess ourselves of the simple notions or concepts, Point, Line, Revolution, we may attain to the notion, Circle, without examining actual circles in the concrete. So we may define an oval, or ellipse, and many other figures. This practice of referring to a simpler order of concepts for the constituents of a given one, is the main function of the Definition, which applies, therefore, to complex notions, and not to such as are ultimate, or simple in the extreme degree. To define in the last resort, we must come to quoting the particulars. We cannot define a line by anything more elementary. To say, with Euclid, that it is length without breadth, is no assistance, as we must still go to our experience for examples of length; and length is not a more simple idea than line, being, in fact, but another word for the same thing. Nevertheless, it has been often supposed that there are general notions independent of all experience, or reference to particulars; the form commonly given to the foundations of the science of mathematics having favoured this view.

The name 'genus' is also connected with the present subject. It is co-relative with another word, 'species,' which, however, is itself to some extent a generalisation; for every species is considered to have individuals under it. Thus, in Zoology, *felis* is a genus of animals, and the lion, tiger, cat, &c., are among its species; but each of those species is the generalisation of an innumerable number of individual lions, tigers, &c., differing considerably from one another, so that to express the species we are still obliged to have recourse to the operations of comparison, abstraction, and definition. Genus and species, therefore, introduce to us the existence of successive generalisations, more and more extensive in their range of application, and possessing, in consequence, a smaller amount of similarity or community of feature (see EXTENSION).

GENERATION. See REPRODUCTION.

GENERATION. A term in use in Mathematics. One geometrical figure is said to be generated by another, when produced or formed by an operation performed upon the other. Thus a cone is generated by making a right-angled triangle revolve about one of its sides adjoining the right angle as an axis. In arithmetic, in the same way, a number is said to be generated when produced by an operation performed on one or more other numbers. Thus, 36 is generated by the involution of 6 to the 2d power, or by the multiplication of 4 and 9.

GENERATION, ETERNAL. See TRINITY, DOCTRINE OF THE.

GENERATION, SPONTANEOUS. From the earliest period to the termination of the middle ages, no one called in question the doctrine that, under certain favourable conditions, of which putrefaction was one of the most important, animals might be produced without parents. Anaximander and Empedocles attributed to this form of generation all the living beings which first peopled the globe. Aristotle, without committing himself to so general a view, maintains that animals are sometimes formed in putrefying soil, sometimes in plants, and sometimes in the fluids of other animals, and lays down the following general principle, 'that every dry substance which becomes moist, and every moist body which is dried, produces living creatures, provided it is fit for nourishing them.' The views of Lucretius on this subject are shewn in the following lines:

Nonne vides quæcunque morâ, fluidoque liquore
Corpora tabuerint, in parva animalia verti?

And Pliny maintains that 'quædam gignuntur ex non genitis, et sine ullâ simili origine.' Virgil's directions for the production of bees are known to

every reader of the *Georgics*, and an expression in the Book of Judges (xiv. 14) probably points to a similar opinion.

Passing from classical times to the later period of the middle ages, and the two succeeding centuries, we may quote amongst the advocates of this theory Cardan—who, in his treatise *De Subtilitate* (1542), asserts that water engenders fishes, and that many animals spring from fermentation—Aldrovandus, Licetus, Gassendi, Scaliger, Van Helmont, who gives special instructions for the artificial production of mice, and Kircher, who in his *Mundus Subterraneus* (in the chapter 'De Panspermia Rerum') describes, and actually figures, certain animals which were produced under his own eyes by the transforming influence of water on fragments of the stems of different plants!

Redi, the celebrated Italian naturalist, whose *Experiments on the Generation of Insects* were published in 1668, seems to have been the first opponent that the doctrine of spontaneous generation encountered. In this work, he proves that the worms and insects which appear in decaying substances are in reality developed from eggs, deposited in those substances by the parents. Leuwenhoek, Vallisneri, Swammerdam, and other eminent naturalists, soon contributed additional facts and arguments in favour of Redi's view; and as from the time of Redi to the present day, the tide of opinion has generally turned strongly against the doctrine in question, it is unnecessary to carry the historical sketch further.

The entozoa, however, continued to be a great stumbling-block. 'When,' says Professor Owen, 'the entozoologist contemplated the *tania* fixed to the intestine, with its uncinated and suctorial head buried in the mucous membrane, rooted to the spot, and imbibing nourishment like a plant—when he saw the sluggish *distoma* (or fluke) adhering by its sucker to the serous membrane of a closed internal cavity, he naturally asked himself how they got there; and finding no obvious solution to the difficulty of the transit on the part of such animals, he was driven to the hypothesis of spontaneous generation to solve the difficulty. It is no wonder that Rudolphi (1808) and Bremser (1824), who studied the entozoa rather as naturalists than physiologists, should have been led to apply to them the easy explanation which Aristotle had given for the coming into being of all kinds of Vermees—viz., that they were spontaneously generated. No other explanation, in the then state of the knowledge of the development of the entozoa, appeared to be adequate to account for the fact of their getting into the interior cavities and tissues of higher animals.' The recent investigations of Von Siebold, Küchenmeister, Van Beneden, Philippi, &c., regarding the development and metamorphoses of the entozoa, have, however, tended to remove nearly all the difficulties which this subject presented; and the advocates of spontaneous generation are fairly driven from this, one of the last of their battle-fields.

The only point at present in dispute is, whether microscopic organisms (animals or plants) may be spontaneously generated. It is well known that if we examine under the microscope a drop of water in which almost any animal or vegetable substances have been infused, and which contains the particles of such substances in a state of decay or decomposition, it is found to swarm with minute living organisms. The question at issue is this: Are these organisms developed in the water, if the necessary precautions have been taken to exclude every animalcule or germ capable of development both from the water and from the air that has

access to it? A well-known experiment, devised by Professor Schulze of Berlin (a description of which may be found in Owen's *Lectures on the Invertebrate Animals*, 2d ed. p. 44), shews that with due precautions in reference to these points, no animal or vegetable organisms are produced. This experiment was continued uninterruptedly from the 28th of May until the beginning of August, 'and when, at last, the professor separated the different parts of the apparatus, he could not find in the whole liquid the slightest trace of infusoria or confervæ, or of mould; but all three presented themselves in great abundance a few days after he had left the flask standing open.' A vessel with a similar infusion, which he placed near the apparatus, contained vibriones and monads on the second day of the experiment, to which were soon added larger polygastric infusoria.

A few years ago, M. Pouchet announced that he had repeated Schulze's experiment with every precaution, but that animalcules and plants were invariably developed in the infusion on which he operated. To prove that the atmospheric air contained no germs, he substituted artificial air—that is to say, a mixture of 21 parts of oxygen gas with 79 of nitrogen. The air was introduced into a flask containing an infusion of hay, prepared with distilled water and hay that had been exposed for twenty minutes to a temperature of 212°. He thus apparently guarded against the presence of any germs or animalcules in the infusion or in the air. The whole was then hermetically sealed, so that no other air could gain access; yet after all these precautions, minute animal and vegetable organisms appeared in the infusion. He repeated the experiment with pure oxygen gas instead of air, and obtained similar results. These experiments are described by Pouchet in the *Annales des Sciences Naturelles* (1858, 4th series, vol. ix. p. 372), and the same volume contains important articles by Milne Edwards, and by De Quatrefages, in opposition to Pouchet's views.

A very large majority of our physiologists of the present day reject the doctrine; most of the apparently exceptional cases, as, for example, the mysterious presence of the entozoa, have been found to admit of ready explanation; and if we do not positively deny the possibility that animalcules may be generated spontaneously, we may at all events assert that such a mode of generation is not probable, and has certainly not been proved to exist. Those who wish to know more fully the arguments that may be adduced in favour of, and in opposition to, the doctrine, are referred, on the one hand, to Pouchet's *Hétérogénie, ou Traité de la Génération Spontanée, basé sur de Nouvelles Expériences* (1859); and, on the other, to Pasteur's *Mémoire sur les Corpuscules Organisés qui existent dans l'Atmosphère; Examen de la Doctrine des Génération Spontanées*, in the *Annales de Chimie et de Physique* (3d ser. 1862, vol. lxiv. pp. 1—110), which seems to place the question beyond the reach of any further discussion.

GENERATIONS, ALTERNATION OF, a phrase devised by Steenstrup, a Danish naturalist, about twenty years ago, to signify 'the remarkable and till now inexplicable natural phenomenon of an animal producing an offspring, which at no time resembles its parent, but which, on the other hand, itself brings forth a progeny which returns in its form and nature to the parent animal, so that the maternal animal does not meet with its resemblance in its own brood, but in its descendants in the second, third, or fourth degree or generation; this always taking place in the different animals which exhibit the phenomenon in a determinate generation,

or with the intervention of a determinate number of generations.'

The phenomenon has been observed in many of the *Hydrozoa*, in various *entozoa*, in *annelids*, in *molluscoids* (*salpæ*), and in insects (*aphides*); and its nature will be best understood by our giving one or two illustrations.

We commence with the development of the *medusæ* or *jelly fishes*, which belong to the class *hydrozoa*. The medusa discharges living young, which, after having burst the covering of the egg, swim about freely for some time in the body of the mother. When first discharged or born, they have no resemblance whatever to the perfect medusa, but are little cylindrical bodies (fig. 1, a), covered

Fig. 1.

with cilia, moving with considerable rapidity, and resembling infusoria. After moving freely in the water for some days, each little animal fixes itself to some object by one extremity (e), while at the opposite extremity a depression is gradually formed, the four corners (b, f) becoming elongated, and gradually transformed into tentacles (c). These tentacles increase in number till the whole of the upper margin is covered with them (g). Transverse wrinkles are then seen on the body at regular intervals, appearing first above, and then extending downwards. As these wrinkles grow deeper, the edge of each segment presents a toothed appearance, so that the organism resembles an artichoke or pine-cone, surmounted by a tuft of tentacles (h). The segments gradually become more separated, until they are united by only a very slender axis, when they resemble a pile of shallow cups placed within each other (i). At length the upper segment disengages itself, and then the others in succession. Each segment (d) continues to develop itself until it becomes a complete medusa (k); while the basis or stalk remains, and produces a new colony. Here, then, we have the egg of the medusa gradually developed into the polypoid organism (h), to which the term *strobila* (from *strobilos*, a pine-cone) has been given. This polype, by gemmation and fission, yields medusæ with reproductive organs.

The phenomenon of alternation of generations in the Cestoid Worms (q. v.), and in certain Trematoid Worms (see FLUKE), has already been noticed, and will be further discussed in the article TAPE-WORMS. The fission of certain annelids (*Syllis* and *Myrianida*), (see REPRODUCTION), presents an example, although at first sight a less obvious one, of alternation of generations, the non-sexual parent worm yielding by fissure progeny containing spermatozoa and ova, from which again a non-sexual generation is produced.

The *Salpæ* (*mollusca* or *molluscoids*) belonging to the family *Tunicata* are usually regarded as affording a good illustration of the phenomenon under consideration. It was in these animals that it was originally noticed by Chamisso, who accompanied Kotzebue in his voyage round the world (1815—1818). The *Salpæ* (from twenty to forty in

number) are united together by special organs of attachment, so as to form long chains, which float in the sea, the mouth (*m*), however, being free in

Fig. 2, A.

each. The individuals thus joined in chains (fig. 2, A) produce eggs; one egg being generally developed in the body of each animal. This egg, when hatched, produces a little mollusc (fig. 2, B), which remains solitary, differs in many respects from the parent, does not produce an egg, but propagates by a kind of internal gemmation, which gives rise to chains already seen within the body of the parent, which

Fig. 2, B.

finally bursts and liberates them. These chains, again, bring forth solitary individuals.

The only instance in which this phenomenon occurs in animals so highly organised as insects is in the *Aphides*, or Plant-lice. In many species of the genus *aphis*, which in the perfect state possess wings, a large proportion of the individuals never acquire these organs, but remain in the condition of larvæ. These without any sexual union (none of them, indeed, being males) bring forth during the summer living young ones resembling themselves; and these young ones repeat the process, till ten or eleven successive broods are thus produced; the last progeny, towards the end of the summer, being winged males and females, which produce fruitful eggs that retain their vitality during the winter, and give birth to a new generation in the spring, long after their parents have perished. Other peculiarities of insect-generation will be noticed in the article PARTHENOGENESIS.

Several high physiological authorities, amongst whom we may especially mention Huxley ('On the Anatomy of Salpæ,' in *Phil. Trans.* for 1851, and 'On Animal Individuality,' in *Ann. of Nat. Hist.*, 2d ser., vol. ix. p. 505), and Carpenter (*Principles of Comparative Physiology*, 1854), object to the term 'alternation of generations.' The detached portions of the stock originating in a single generative act are termed *Zooids* by these writers, whilst by the term *animal* or *entire animal* (the equivalent of *Zoon*) they understand in the lower tribes, as in the higher, the *collective product of a single generative act*. Here they include under the title of *one generation* all that intervenes between one generative act and the next. 'If,' says Dr Carpenter, 'the phenomena be viewed under this aspect, it will be obvious that the so-called "alternation of generations" has no real existence; since in every case the whole series of forms which is evolved by continuous development from one generative act repeats itself precisely in the products of the next generative act. The alternation, which is very frequently presented in the forms of the lower animals, is between the products of the *generative act* and the products of *gemmation*, and the most important difference between them usually consists in this—that the former do not contain the generative apparatus which is evolved in the latter alone. The generating *zooid* may be merely a segment cast off from the body at large, as in the case of the *Tape-worms* (q. v.), or it may contain a combination of generative and locomotive organs, as in the

self-dividing *Annelide*. It may possess, however, not merely locomotive organs, but a complete nutritive apparatus of its own, which is the case in all those instances in which the *zooid* is cast off in an early stage of its development, and has to attain an increased size, and frequently also to evolve the generative organs, subsequently to its detachment; of this we have examples in the *Medusæ* budded off from Hydroid Polypes, and in the aggregate *Salpæ*.'—*Principles of Comparative Physiology*, p. 529.

GENESEE, a remarkable river of North America, rises about 10 miles south of the boundary between the states of Pennsylvania and New York, flows north through the western portion of the latter state, and after a course of 145 miles falls into Lake Ontario, 7 miles north of the city of Rochester. The G. is not only notable for the varied and romantic character of its scenery, but is also famous for its extraordinary falls. Of these falls, which are five in number, three, occurring within a distance of two miles, in the vicinity of the town of Portage, about 90 miles from the mouth of the river, are respectively 60, 90, and 110 feet high. The other two, the one occurring immediately above Rochester, and the other about 3 miles below that city, are both of about 100 feet.

GENESIS, or more fully GENESIS KOSMOU (Origin, Generation of the World), is the name first given by the Septuagint to the opening book of the Pentateuch. In the Hebrew canon it is called *Beresith* (In the Beginning), from the initial word; in the Talmud, it is sometimes referred to as 'The Book of Creation,' or 'The Book of Abraham, Isaac, and Jacob.' Its Masoretic division into fifty chapters, followed in the English Bible, or into 12 large and 43 small encyclical sections (*Sedarim*, *Parashoth*), has been grounded rather on convenience than on any corresponding division of the subject-matter. The book seems of itself to fall most naturally into two totally distinct parts: the first of which would extend from the beginning to the call of Abraham (c. i.—xii.), and embrace the account of the creation, paradise, fall, the generations between Adam and Noah, together with their religion, arts, settlements, and genealogy, the deluge, the re-peopling of the earth, the tower of Babel, the dispersion of the human race, and the generations between Noah and Abraham: thus forming an introduction to the second part (c. xii.—l.), or the history of the patriarchs (Abraham, Lot, Ishmael, Isaac, Jacob, Esau, and Joseph); the whole concluding with the settlement of Jacob's family in Egypt. Another division seems indicated by the inscription *Toledoth* (Origin, Generation), which occurs ten times in the course of the book, introducing at each repetition a new cycle of the narrative, and which would thus split the whole (from c. ii. 4) into ten distinct sections of disproportionate length.

The period of time over which the Book of Genesis extends has been variously computed; the number of years commonly assigned to it is about 2300; the variations in calculation seldom exceeding units or tens of years; Bishop Hales alone, following the Septuagint, reckons 3619 years.

Being a portion, and the introductory portion of the Pentateuch—at the same time that it forms a complete whole in itself—it cannot but be considered as laying down the basis for that theocracy of which the development is recorded in the succeeding books. While the design and plan of the Pentateuch is thus also that of Genesis, the latter, however discordant its constituent parts may seem, does not lack the necessary unity. Beginning with the cosmogony, or rather geogony, i. e., the

generation of the earth with its animate and inanimate products, and all created things which bear upon and influence it visibly, the record gradually narrows into the history of man, and with the distinct aim of tracing the fate of the one chosen family and people, it singles out Noah, Abraham, Isaac, Jacob. The narrative dwells with careful minuteness upon their fortunes, laying especial stress on their intimate communion with God, and, with the three last, on the reiterated promises of the land which they should inherit: 'they and their seed after them.' The remainder of the human race is summarily treated of; the various founders of tribes and peoples that represent it being generally but briefly named. It is only in the case of brothers, or very near relations of the elect, that certain incidents of their lives are more fully recorded; plainly with the intention of proving the inferiority of their claims to divine consideration, or even of representing them as meet objects of the displeasure of the Almighty:—Ham, Ishmael, Esau. From c. xxxvii. to the end of the book, we have exclusively the one chosen family of Jacob and his children before our eyes; and the strictly national character, which the narrative now assumes, excludes everything but the fortunes of this particular house. Here, also, an unbroken, flowing style takes the place of the former apparently sketchy and sometimes abrupt manner. With the occupation by Jacob's rapidly developing tribe of the land of Goshen, this first great patriarchal period is brought to a fitting close, and the second ushered in, when the tribe reappears after a lapse of time as a people. The Maker of all things, having by the creation of one man and one woman placed all mankind on an equal footing, by his sovereign will subsequently elected one righteous from out the mass of human corruption, and through this man's progeny—whose history is told at length—mankind is in the end to be reclaimed:—this seems the pith of the book, considered as a religious history of man.

A certain apparent difference of style and language; the occurrence of what seemed gaps on the one, and repetitions and contradictions on the other hand; the special headings (*Toledoth*) above mentioned; and, lastly, the different use of the term for the divine name, led very early to the question of the integrity of Genesis. Celsus, Isaac, C. Jasco, Aben Ezra, Karlstadt, Spinoza, all assumed smaller or larger interpolations; that is, pieces evidently not written by the author of the book himself, but added afterwards. It was not before 1753 that the 'Hypothesis of Documents,' based on the alternate use of the word *Jehova* (Everlasting) and *Elohim* (Almighty) was first broached. While the Talmud, Tertullian, St Augustine, Chrysostom, Jehudah Hallevi, &c., had all endeavoured to explain how the individual word was always necessary in the special passage where it occurred, Astruc, a Belgian physician, published in that year his *Conjectures sur les Mémoires originaux dont il paroit que Moïse s'est servi pour composer le livre de Genèse*, in which he endeavoured to shew that this writer, or rather editor of the book, had made use of two large and ten small—respectively 'Elohistic' and 'Jehovistic'—documents for his composition. This theory was at first received with silent contempt in the writer's own country. The only man who took any notice of it was Charban, who at the same time excused himself for refuting this 'absurd but dangerous' theory. It soon, however, found its way to Germany, where it was warmly advocated and developed by Eichhorn (*Repert. and Introd.*), Ilgen, and Gramberg. A further step was taken by Vater and Hartmann, to whom belongs the 'Hypothesis of Fragments,' or of

the whole Pentateuch being a Mosaic of fragments by various authors. Both these notions have now been pretty generally rejected, chiefly on account of their incompatibility with the apparent unity of the whole work and its single parts. The theory adopted by the majority of biblical critics of our day, among whom may be mentioned Wette, Leake, Knobel, Stähelin, Bleek, Tuch, Delitzsch, and Bunsen, is the 'Complementary,' according to which the author of the Pentateuch—the Jehovist—had worked upon an old Elohistic fundamental record which embraced the time from the creation to the death of Joshua, altering, enlarging, and completely rewriting it. Ewald and Hupfeld, however, assume four writers; the former two Elohists and two Jehovists, the latter three Elohists and one Jehovist; while the apologetic school of Hengstenberg, Hävernick, Keil, attempts to uphold the primitive theory of one single author.

Considered from the remotest time as a book written under the influence of divine inspiration—a term very differently understood—and thus raised above all doubt as to its truthfulness, various efforts were made, from the days of the earliest interpreters to our own, to explain, by allegory and symbol, such of its statements as in their plain sense seemed incomprehensible to human understanding. Philo and the Alexandrines generally, Papias, Irenaeus, Justin Martyr, and others, in all seriousness spiritualised into divine parable that which was given as history; so much so, that St Augustine—exemplifying the spirit of the times—shortly after his conversion, explains paradise to represent nothing more than the happiness of mankind, the four rivers the four virtues, the serpent the devil, the coats of akin immortality, &c. In more recent times, however, after Luther had restored the belief in the literal meaning of the text, some have gone so far as to refer all that is not within the grasp of human reason to the region of myth, and to point to the obvious similarity between the biblical narrative of the paradise, its four rivers, the serpent, the apple, the fall, &c.; and certain legends, common to most eastern nations in the remotest times, as a proof that they were all derived from one and the same mythical source. Since the revival of science in the 16th c., another and much graver difficulty, however, has arisen—viz., how certain distinct and explicit statements of the Scripture, allowing of but one translation, were to be reconciled with certain undeniable physical facts. It is more especially the Mosaic cosmogony, as contained in the opening chapters of Genesis, which has given rise to violent controversies. The age of the world, which, according to the Bible, would be 6000, or at most, between 7000 and 8000 years; its creation and the formation of the whole system of the universe in six days; have been declared by astronomers and geologists, who reckon the period of the existence of the earth by millions, of the universe by millions upon millions, to be subjects on which information must be sought elsewhere than in the Bible. Most of the apologists have to a certain degree granted this, and they only differ among themselves as to the extent to which the Bible, a book intended for religious instruction exclusively, has reserved such knowledge as has been or may be acquired by scientific investigation. The words of the biblical record themselves, so far from being in contradiction to the results of human knowledge, are said to convey, if not directly, yet by implication all that science more plainly teaches. The two principal methods of reconciliation advanced in this country are those of Dr Buckland and Hugh Miller (and their followers) respectively, the first of whom adopts and amplifies the Chalmersian

interpolation of the geological ages before the first day (an opinion strangely enough to be found already in the *Midrash* (q. v.): 'Before our present world, the Almighty had created worlds upon worlds, and destroyed them again'), the latter the Cuvierian expansion of the six days into geological ages. On the other hand, it is asserted both by those who hold that the Bible is entirely the work of man, and by those who take it as a mixture of the divine and the human element, that the biblical notion of the cosmogony, as well as of all the other physical phenomena, are simply in accordance with the state of science in the days when the book was compiled.

The apologists adduce, as a further proof of the authenticity of the Bible, the surpassing sublimity and moral superiority of its cosmogony as compared with all others. The dualism of God and matter, which, according to the different pagan systems, are either eternally co-existent or fused into each other, is exchanged for the awful and moving idea of a one personal God, who first created, then moulded, and everlastingly sustains the universe, lavishing his highest gifts on man, made in his own image, and standing towards him in the living relation of a son to a father. The occurrence of similar traditions in the religious records of other primeval nations is taken as a corroborating proof of the historical truth of the biblical account. Recent investigations have likewise affirmed the division of mankind into three principal races, corresponding to Shem, Ham, and Japhet, to be substantially correct, as far as language is concerned.

The question whether Moses really was the author or compiler of Genesis has been negatived by some, chiefly on the ground that certain apparently obsolete names mentioned are explained by others which first came into use at a much later time, and that there are allusions made to events which happened centuries after Moses. Graves, Faber, Rosenmüller, and others, consider such passages to be late additions. The further question whether Moses wrote it while at Midian, or during the forty days on Mount Sinai, or during the forty years' sojourn in the desert, will be considered in the article *PENTATEUCH*, where also some other points in connection with the composition of this book will be glanced at. Of opinions on the other side, we will briefly mention that of Lengerke, who holds the Elohist to have written under Solomon, and the Jehovist under Heseekiah; of Tuch, who places the former in the time of Saul, the latter in that of Solomon; and of Bleek, who assigns to the Elohist the time of Saul or the Judges, and to the Jehovist the beginning of David's reign.

Of the infinite number of ancient and modern writers who have commented on Genesis, we will mention Cyril of Alexandria, Ephraem Syrus, Theodoret, Procopius, Chrysostom, Jerome, Augustine, Jitachaki (commonly, but wrongly, called Jarchi), Aben-Ezra, Levi b. Gershom, Abrabanel, Mendelssohn, Michaelis, Vater, Bohlen, Rosenmüller, Eichhorn, Augusti, Faber, Graves, Schumann, Tuch, Knobel, Herder, Hamann, Baumgarten, Delitzsch, Hengstenberg, Keil, Kalisch, Kurtz, &c. See also Turner's and Hävernick's *Introductions to Genesis*; Hugh Miller's *Testimony of the Rocks*; Pye Smith's *Relation between Scripture and Science*; Dr Whewell's *Bridgewater Treatise*; Goodwin's *Mosaic Cosmogony*, &c.

GENET (*Genetta*), a genus of quadrupeds of the family *Viverridae*, nearly allied to the Civets (q. v.), but having only a rudimentary odoriferous pouch, and claws perfectly retractile, as in the *Felidae*. The approximation to that family also appears in the vertical contraction of the pupil of the eye.

The species are numerous; smaller and more slender animals than the civets, mostly natives of Africa and the warmer parts of Asia. One, the common G. (*G. vulgaris*), is found in the south of Europe, as

Genet (*Genetta vulgaris*).

well as throughout Africa. It is gray, with small round or oblong black or brown spots; the tail, which is as long as the body, ringed with black and white. It frequents the banks of brooks. Its fur is a considerable article of commerce. It is easily domesticated, and is kept in houses in Constantinople to catch mice.

The **GENET** is sometimes met with in Heraldry. There was an order of knighthood in France, founded by Charles Martel, called the order of the G., but it has long ceased to exist.

GENEVA (Fr. *Genève*, Ger. *Genf*, Ital. *Ginevra*), the most populous and flourishing town of Switzerland, capital of the canton of the same name, is situated on the southern extremity of the Lake of Geneva, 70 miles north-east from Lyon, in France. At the time of the contests between the Helvetii and the Romans, G. belonged to the country of the *Allobrogi*. It was afterwards included in the Roman *Provincia Maxima Sequanorum*, and was a place of some importance under the Burgundian kings. On the dissolution of the kingdom of Burgundy, G. fell under the dominion of the Ostrogoths; in the year 536, under that of the Franks; and towards the end of the 9th c., under the new kingdom of Burgundy. It had been made a bishop's seat in the 5th c., and from the 12th c. continual feuds arose between the bishops and the Counts of Savoy with regard to the supremacy. The citizens took advantage of these dissensions to obtain fresh liberties and privileges for themselves. In 1516, the Genevans concluded an alliance with Freiburg, and shortly after with Bern, and thus G. became a member of the Swiss confederation.

The doctrines of the Reformation, boldly and enthusiastically preached by William Farel, met with general acceptance in Geneva. In conjunction with Bern, the citizens expelled the adherents of the Dukes of Savoy—the so-called *Mamelukes*—from the town, and declared the bishopric vacant. In August 1536, the Reformed religion was established by law; and in 1541, Calvin was invited to take up his residence permanently in G., as public teacher of theology. It was he who chiefly impressed the stamp of rigid morality, not unalloyed with pedantry, on the minds of the citizens of G., and awakened a taste for the exact sciences. The town, which had hitherto been merely a place of trade, thus acquired an important influence over the spiritual life of Europe, and became the centre of education for the Protestant youth of Great Britain, France, Germany, and

GENEVA.

Spain. In 1602, the last attempt of the Dukes of Savoy to recover the town was frustrated by the energy and resolution of the citizens.

During the 18th c., G. was distracted by a continued feud between the aristocratic and popular parties, until in 1792, Bern, Sardinia, and, in particular, France, interfered in favour of the aristocracy. The French Revolution led to a new crisis; the government was overthrown in July 1794, equality in the eye of the law was established, a national convention appointed, and a reign of terror commenced. In 1798, G., and its territory, was annexed to France under the name of the department 'Du Leman.' After the overthrow of Napoleon, G. recovered its independence, and the Congress of Vienna increased its territory considerably.

The situation of the town on both sides of the lake where it is narrowed to a point and forms the Rhone, is exceedingly pleasant and advantageous for traffic. Formerly, G. was surrounded by walls, and consisted of clusters of narrow and ill-drained streets; but since the accession of the democratic party to power in 1847 (see next article), a most extraordinary change has been effected, and chiefly through the energy and enlightened views of M. James Fazy, a wealthy native proprietor. The ancient ramparts have been removed, streets widened and well paved, new and commodious quays constructed along the shores of the lake and river, and a spirit of improvement introduced which points to a great extension of the city. Among the latest improvements is the construction of a breakwater, within which, as in a harbour, steam-boats are received and lie in safety, and from which they depart several times daily to the principal ports on both sides of the lake. The two divisions of the town are connected by several wooden bridges, and at present (1862) a new stone bridge is in the course of construction. In rushing through the town, the Rhone parts into two branches, forming two islands, on one of which still exists an antique and picturesque cluster of buildings; on the other, laid out as a public pleasure-ground, there is a statue of Jean Jacques Rousseau, who was a native of the town. Stretching along a part of the new quay, on the left side of the Rhone, there is now a public promenade laid out as a *jardin Anglais*. As forming a central terminus for French and Swiss railways, G. is a favourite resort of travellers, for whose accommodation there are several large and splendid hotels, commanding fine views of the lake and mountain scenery in the environs. The language spoken is French. The principal edifices are the cathedral church of St Pierre, which dates from 1124; the town-hall; the college, founded by Calvin in 1558, and containing a library of 40,000 volumes; the Musée Rath, so called from the name of its founder, General Rath, and containing good pictures; the observatory, the finest in Switzerland; and the museum of natural history, containing De Saussure's geological collection, Haller's herbarium, the fossil plants of Brogniart and Decandolle, &c. The university (originally established in 1368, and reorganised by Calvin and Beza in 1539) has four faculties—theology, law, science, and belles-lettres. Among the many handsome new public buildings may be mentioned the Post-office, a Catholic and an English church, this last accommodating the large number of English residents and casual visitors. The staple manufactures of the town are watches, musical-boxes, and jewellery; and for the sale of these and other fancy articles, there are many attractive shops. Altogether, G. is to be considered as now one of the most prosperous and improving

towns on the continent. In 1860, the population of the city and suburbs was 41,756.

GENEVA, a canton of Switzerland, in the south-west of that country, is bounded on the N. by the canton of Vaud and the Lake of Geneva, and on the S., E., and W., by the territories of France. It has an area of 109 square miles, and in 1860 it had 83,395 inhabitants, of whom 42,355 were Catholics. It is watered by the Rhone and the Arve, which unite about two miles from the south-west extremity of the Lake of Geneva. The surface is hilly, and the soil, not naturally fertile, has been rendered so by the industry of the inhabitants. The political affairs of the canton and city have undergone various changes, the last of these being a revolution in 1847, when the old aristocratic party was overthrown, and a democratic and progressive party attained to power. Long inert, and in a backward condition, the administration is now most active in developing the resources of the canton. According to the constitution of 1847, all male citizens of 21 years of age exercise the right of electing representatives to the cantonal council; the age of members of which must be at least 25 years. There is a representative for every 666 inhabitants. The executive is confided to a council of state composed of 7 members, nominated for 10 years, but eligible for re-election. The constitution guarantees civil and religious liberty, all forms of worship being allowed by law; but the majority of the citizens pertain to the Reformed Calvinistic Church. The chief branches of industry are agriculture, and the manufacture of articles of *bijouterie* and watches. About 100,000 watches are made annually, and exported to France, England, Italy, and elsewhere. Musical-boxes, chronometers, mathematical instruments, &c., are also made. The chief town is Geneva (q. v.).

GENEVA, a village of North America, in the state of New York, is delightfully situated at the north-western extremity of Seneca Lake, 200 miles west of Albany, and 50 miles south-east of Rochester. It is handsomely built, and commands a magnificent view of the lake and the surrounding country. Its principal institutions are the Episcopal church, a Gothic structure in stone; the Geneva Medical College, and the Hobart Free College. This institution, called the Geneva College till 1852, was established here in 1824, and in 1858 it had five professors besides the president, and 96 students. Pop. (1855) 5057.

GENEVA, LAKE OF, or the Leman Lake (*Lacus Lemanus*), situated between Switzerland, to which the larger portion belongs, and the recently acquired territories of France. It lies 1150 feet above the level of the sea, and extends for rather more than 50 miles from east to west, in the form of a crescent. Its greatest breadth is eight miles, and its depth between Evian and Ouchy is 920 feet. This lake at some periods of the year presents a curious phenomenon, which has never been sufficiently accounted for, the surface, especially near Geneva, rising and falling through a space of from two to five feet in the course of about 25 minutes. The lake, which is never entirely frozen over, abounds in fish, and several steamers ply upon its waters. The shore on the side of the Pays de Vaud is celebrated for the beauty of its scenery; the southern French shore rises solemn and stern, with the mountains of Savoy in the background. From the Lake of Geneva, Mont Blanc is visible, and although 60 miles distant, is often reflected in its waters. The Rhone enters the lake at the upper end, turbid and yellow, and leaves it at the town of Geneva as clear as glass, and of a deep blue

GENEVIEVE—GENGHIS.

tint. The lake receives about 20 streams from its northern shore, none of which, however, are important.

GENEVIEVE, a saint of the Roman Catholic Church, the subject of many popular and highly poetical legends, and regarded with special veneration in France and particularly in Paris, of which city she is the patroness. From a nearly contemporary life of St. G., we learn that she was born in 422, in the village of Nanterre, near Paris, where, as a mere child, she attracted the notice of Germanus of Auxerre, who passed a night at Nanterre on his return from Britain in 429. Germanus is said to have marked her out as specially destined to a life of holiness and purity; and the child, partly from her natural tendency, partly, perhaps, under the influence of the counsel of so holy a bishop, devoted herself to a life of virginity and conventual seclusion. On the death of her parents, she was removed to Paris; and her active charity, and the extraordinary reputation for sanctity which she acquired both there and in other cities of France, which she visited on missions of Christian benevolence, won for her the admiring veneration, not alone of her own people, but even of the heathen or half-converted tribes, which, about this period, after a long series of struggles, had begun to amalgamate with the ancient population of the Roman province of Gaul. During the Frank invasion under Childeric, G., with her sisters in religion, set out on an expedition for the relief of the starving city, and successfully conveyed to Paris an abundant supply of provisions. The city, when taken, was treated with special leniency through her intercession with the king, and many captives obtained their liberty at her prayer. On the new alarm for the safety of Paris, created by the news of the march of Attila and his army of Huns, it was proposed to abandon the city; but G., assembling the matrons and consecrated virgins in one of the churches, exhorted them to avert, by prayer and fasting, the threatened calamity. The unexpected alteration of the direction of Attila's march added still more to her reputation and to her influence; and it is agreed that her personal example, and that of the sisterhood to which she belonged, appealed, with no inconsiderable effect, to the natural sensibilities of the rude races which now found themselves, for the first time, in contact with the humanising influences of the Christian religion. St. G. enjoyed, to an extreme age, the reverence and love of the entire people. She died in 512 at the age of 89, and her memory is still affectionately described as the type of all that is purest and most elevating in the conventual life, as well as of all that is most admirable in the works of charity and benevolence, with which, in the active orders, that life is habitually associated. Under her patronage, and with her name, a religious congregation of priests was founded in the 12th c., which, with some vicissitudes, continued until the Revolution. A religious congregation of women, under the name of 'Sisters of St. Genevieve,' was established in 1636, chiefly devoted to the care of the sick and the education of young females.

GENGHIS (Jengueiz, Tchinggis, or Zingis) **KHAN**, originally called Temujin, a celebrated Mongol conqueror, born 25th January 1155 A.D. at Deylun-Yeldak, near the northern bend of the Feramuran (Hoang-Ho), was the son of Yesukai Bahâdur, a Mongol chief, who ruled over some thirty or forty families or clans, called the tribe of Neyrun, who dwelt between the Amur and the great wall of China, and paid tribute to the khan of East Tartary. On his father's death, he did not

hesitate to assume the reins of government, though only 13 years of age. Some of the subject tribes refused to obey him, and chose another chief belonging to the same family. A war of several years' duration was the result, at the termination of which he was compelled to retire to Karakorum the capital of Toghrul Ungh-Khan, monarch of the Keraeit, and place himself under that monarch's protection. Ungh-Khan gave him his daughter in marriage, and appointed him to the command of his army, in which capacity G. gave proof of great military talent, conquering the Mekreit, Tanjût, Jellâir, and other neighbouring tribes. But Ungh-Khan, becoming jealous of his growing reputation, and urged on by envious courtiers, ordered G. to be assassinated. The latter, having taken counsel with his relative and chief councillor, Karatchâr Nuyan, a youth of his own age, but renowned in Tartar history for his wisdom, resolved to depart for his native country, which, after many hair-breadth escapes, he reached at the head of 5000 cavalry. Raising an army, he marched against his father-in-law; and Toghrul, vanquished in battle in 1203, sought refuge among the Naymans, but was slain by the guards stationed on the frontier. G. immediately seized upon Toghrul's dominions. In the following year, a number of Tartar tribes, alarmed at his increasing power, formed a powerful league against him. The command was given to Tai-Ungh-Khan, chief of the Naymans; but in a battle fought on the banks of the Amur, G. utterly routed his enemies, slew their leader, and became at once master of almost all Mongolia. Grand views of conquest seem now to have opened before his vision. In the year 1206, he convoked a kouriltai, or general assembly, on the banks of the Onan, a tributary of the Amur, flowing through his native land. This meeting was attended by deputies from all the subjugated hordes of Tartary, and G. contrived to obtain a religious confirmation of his designs. Up to this period, he had borne the name of Temujin; but a renowned magician or priest, surnamed Bout-Tangri ('Son of Heaven'), venerated by all the Mongols, now came forward and pronounced him *Genghis Khan*—i.e., greatest of khans, or khan of khans, declaring that he should rule over the whole earth. The deputies were duly impressed. About this time the Eighurs, an agricultural and civilised people, inhabiting the country at the sources of the Hoang-Ho and Yang-tse-Kiang, voluntarily submitted to his sway. From this people, who professed Buddhism, the Mongols would appear to have acquired a knowledge of writing. They adopted the Eighur characters, but preserved their own language, and G. selected one of the newly-submitted tribe to instruct his children. The next important incident in his career was the conquest of the northern portion of China, called Khatai. The immediate cause of the war between G. and the emperor of China, Tchong-Héi, was the refusal of the former to recognise the latter as his suzerain, or liege-lord. Most of the Tartar tribes which G. had subdued were really tributaries of the Chinese empire; and Tchong-Héi, though not interfering to prevent the conquests of the Mongols, now wished G. to acknowledge his superiority by paying tribute. G. immediately prepared for war, scaled the great wall in 1211, and after a series of bloody and protracted campaigns, Pekin fell into the hands of the barbarians in 1215. Meanwhile G. was called back to Tartary to quell certain insubordinate tribes, headed by Gutchluk, son of the chief of the Naymans, who had recovered his ancestral dominions, and also conquered those of the Gûr-Khân of Kara-Khatai. These tribes were nearly exterminated in a great

fight which took place near the sources of the Yenisei. Gutchluk, however, had some time before taken refuge in Turkestan, a vast region stretching from Lake Lob, in the middle of Tartary, westward to the Sea of Aral. Here he succeeded in making himself supreme ruler, but only to be swept away by the victorious Mongols, now pressing westward in an irresistible torrent. At length G. reached the Sihoon, the north-eastern boundary of the empire of Khaurezm or Kharizm, whose ruler, Ala-ed-din Mohammed, was one of the most powerful sovereigns in Asia. The dynasty to which he belonged had risen into power through the weakness of the Seljuk sultans; and its sway now extended from the borders of Syria to the river Indus, and from the river Sihon to the Persian Gulf. The murder of some Mongol merchants at Otrar, a town on the Sihon, afforded G. a pretext for invasion. He immediately despatched his eldest son, Jöjy, at the head (according to Eastern chroniclers) of 700,000 horse, who accordingly burst into Khaurezm in 1219; and after having overthrown the Tartar allies of Sultan Mohammed, and fought a long and bloody battle with the sultan himself with no decisive result, captured Samarkand, Bokhara (the valuable library of which he destroyed), and all the other important cities of the country. The Mongols, in three separate divisions, now scourged and ravaged Khaurezm in all directions. In the course of five or six years, they overran the whole of Persia, subdued the inhabitants of the Caucasus, crossed into Russia, and plundered the land between the Wolga and the Dnieper. Nor were they less successful in the east; the whole of Southern Asia, as far as the Sutlej, experiencing the miseries of their devastations. Sickness, disease, and exhaustion at length enfeebled the Mongol hordes, and compelled G. to return to Karakorum, in Tartary, the capital of his empire, in 1224. During his absence, his generals had been prosecuting the Chinese war with the greatest success. G., though well-advanced in years, was still possessed by the old thirst of conquest; and having recruited his forces, he led them across the great desert of Gobi to the kingdom of Tanjout, in the north-west of China, the capital of which, Nin-hia, he besieged. Disheartened by the loss of the greater part of his army, the king of Tanjout promised to capitulate at the end of a month; but in the interval G. died, the 24th August 1227, on the hill Liou-pan, worn out with years and toils. G. is said to have had five hundred wives and concubines, and to have left a great number of children, among three of whom he divided his enormous possessions. The third son, Oughtai, was appointed 'Grand Khan,' and received for his share the country now called Mongolia, with Khatai or Northern China as far north as the mouth of the Amûr. The second son, Tcheghatai, received Turkestan north of the Amûr or Jeyhûn, and was committed to the guardianship of Karatchâr Nuyan. Jöjy, for his share, obtained Keptchâk, and all the country west and north of Turkestan, an immense tract extending from the Caspian Sea almost to the Northern Ocean.

In the course of his sanguinary career, G. is said to have destroyed, by wars and massacres, no fewer than five or six millions of human beings. His conquests were generally accompanied with acts of appalling barbarity, yet we seem to trace through the dreadful history of the man some indications of a civilising tendency. Himself a Monotheist, a stern believer in God after the fashion of Mohammed, he nevertheless tolerated all religions; exempted from taxes and military service physicians and priests; made obligatory the practice of hospitality; established severe laws against

adultery, fornication, theft, homicide, &c.; organised a system of postal communication throughout his enormous dominions (mainly, no doubt, for military purposes); and so thoroughly organised what we may call the police or civil authority, that it was said one might travel without fear or danger from one end of his empire to the other. He would also appear to have had a respect for men of learning and virtue, and to have retained several of such about his person. The only memorial of G. now known to exist is a granite tablet, with a Mongol inscription (deciphered by Schmidt of Petersburg), discovered among the ruins of Nertschinsk. This tablet had been erected by G. in commemoration of his conquest of the kingdom of Kara-Khatai.

GENII. According to the belief of the old Italian races, genii were protecting spirits, who accompanied every created thing from its origin to its final decay, like a second spiritual self. They were appropriated not only to men, but to all things animate and inanimate, and more especially to places. They were regarded as effluences of the Divinity, and were therefore worshipped with divine honours; sacrifices were annually made to them on various occasions, especially on birthdays, and during the period of harvest. Nay, Jupiter himself was called the genius of men, and Juno of women. Not only had every individual his genius, but likewise the whole people. The statue of the national genius was placed in the vicinity of the Roman forum, and is often seen on the coins of Hadrian and Trajan. The genius of an individual was represented by the Romans as a figure in a toga, having the head veiled, and the cornucopia or patera in the hands; while local genii appear under the figure of serpents eating fruit set before them. (Compare Hartung *Die Relig. der Röm.* l. p. 32, &c., and Schömann *De Dis Manibus, Laribus, et Geniis*, Greifswald, 1840.)—The GENII of the East bear no resemblance to the old Italian genii. Their proper Arabic name is *Djinn* or *Jinn*; and there seems to have been no better reason for translating the word by the Latin term *genius*, than the casual similarity of the sounds. The word *Djinn* is from an Arabic root, signifying to 'veil' or 'conceal,' and properly denotes an 'invisible being.' The djinns, or Eastern genii, are, in fact, regarded by the Arabs and Persians as an intermediate class of beings between angels and men, and inferior in dignity to both. They are described in poetry as the subjects of a certain Jân Ibn Jân, and as inhabiting the world before the present race of human beings; but they having excited the anger of God by their rebellion, he sent his favourite angel, Hhâris, or according to others, Azazel, to punish and govern them. Some time after, Hhâris himself rebelled, whereupon God condemned him to eternal punishment. From this period, on account of his despair or his apostasy, he was called Eblis or Iblis. The djinns can assume, in an instant, any form they please, whether of man, brute, or monster, the last—in accordance with the popular view of their wicked character—being the one most frequently selected. Such as have read the *Arabian Nights* will have a vivid recollection of the hideous and gigantic shapes under which the genii are wont to manifest themselves, accompanied at times with smoke and thunderings, to terror-stricken mortals. They are in no degree whatever *guardian* spirits like the genii of the old Italians; on the contrary, they are inimical to man's happiness, and can only be subdued by the spells of powerful magicians. See FAMILIAR SPIRITS. The better-informed Easterns, however, do not believe, it is said, in the actual existence of such beings. The Mussulman doctors, it is true, affirm the existence of djinns

as an invisible race of supernatural beings, who carry out the purposes of Deity, but they reject altogether the grotesque and repulsive inventions of the Arab and Persian romancers and poets.

GENIPAP, a much esteemed fruit of the West Indies and warm parts of South America. The tree which yields it is *Genipa Americana*, of the natural order *Cinchonaceae*. It is a 2-celled berry, containing many seeds; about as large as an orange, of a whitish-green colour, with a dark purple juice of an agreeable vinous taste.

GENISTA, a genus of leguminous plants, of which the characters are noticed in the article BROOM. Some of the species are popularly known by the name Broom, some as GREENWEED (q. v.). *G. Anglica*, a much branched, very spiny shrub, not above a foot high, is called PETTY WHIN and NEEDLE FURZE in England, where it is regarded as indicating a very poor soil. The *Genista* of Virgil and other Roman classics is supposed to be *G. Hispanica*, a native of the south of Europe, with branched stiff spines. *Gen* is said to be a Celtic word, signifying a shrub. The name *Plantagenet*, is from *Planta Genista*; but what plant was intended, and whether the common furze or a species of *Genista*, is not so certain.

GENITIVE, the name of one of the 'cases' in grammar (see DECLENSION). In such an expression as (Lat.) *regis filius*, (Eng.) the *king's son*, the form *regis* or *king's* is called the genitive case; and according to the usual explanation, this name was given it, because it indicates the source or origin of the thing joined with it. A much more satisfactory account of the origin of the name, and of the real nature of the genitive case, is that given by Max Müller (*Science of Language*). The terms of grammar were originally applied, not to the parts of speech, but to the elements of thought; they were logical terms before they were grammatical. Long before the now familiar grammatical distinctions of singular and plural, of gender, case, voice, &c. had been thought of, the Greek writers on dialectics, in analysing the different parts of an expressed thought, had distinguished the principal notion—the subject or nominative as it is called—from secondary or dependant notions; the dependency of the latter they expressed by the word *ptosis* (Lat. *casus*), a fall or leaning of one thing upon another; and in such a proposition as, 'the king's son is dead,' they indicated the exact nature of the dependence by calling it the *genikē ptosis*, i. e., the case shewing the genus, kind, or class—the generic case; for while the name 'son' is applicable to every man having parents, 'king's son' is limited to the class of sons having kings for their fathers. One name joined to another in this relation has thus the same effect as an Adjective (q. v.) in limiting its application. It seems probable, indeed, that the termination of what we now call the genitive case, was originally the same as that by which adjectives were formed from nouns. The names thus applied to ideas were by the Greek grammarians of Alexandria transferred to the words expressing them, and were afterwards translated into their Latin equivalents by the Greek grammarians who taught their language to the youth of Rome. But by this time the terms had become strictly technical, and their original signification little thought of; and this may account for the Greek *genikē*, the Latin equivalent for which is *generalis*, being rendered by *genitivus*, generating or producing, which would have been expressed in Greek by *gennetike*.

In English, the genitive is the only case or relation among nouns expressed by a difference of termination, and even it is often expressed by the preposition

of; as the *river's* brink, or the brink of the *river*. From the frequency with which the form is 's indicates that one thing belongs to another, it is often called the *possessive* case. But this name is little applicable in such expressions as a *day's* journey; still less in many cases where the genitive is used in the ancient languages; e. g., *fons lactis*, a fountain of milk. The *generic* case, however, meaning that which limits the other noun to a class or kind, will be found to express the real relation in every conceivable combination.

The termination 's has been erroneously supposed to be a contraction for *his*, as if 'the king's son' = 'the king his son.' But this would not account for 'the queen's son,' or for 'men's sons.' Besides *his* itself is the genitive of he, and formed in the same way as *king's*, for the apostrophe (') is a mere artificial expedient of writing to distinguish the possessive from the plural, and does not belong to the spoken language. The English genitive in 's is a genuine relic of the Inflections (q. v.) common at an early stage to all the Aryan languages. *s* was the prevalent ending of the genitive singular in the Anglo-Saxon, and in modern English it has been extended by analogy to all nouns and even to the plural. When the plural ends in *s*, the additional *s* of the genitive is omitted, for the sake of the sound, as *kings' sons*.

GENIUS. This word, which conveys the most lofty eulogium that can be applied to intellectual excellence, meant originally the tutelary god or demon that was anciently supposed to preside over the birth and destinies of every individual human being. The peculiarities attending the character and career of each person came thus to be attributed to the higher or lower nature of their attendant genii. Thus arose one of the meanings now attached to the word—namely, the special bent, aptitude, or faculty, which any one possesses; as a genius for poetry, for music, for mathematics, for statesmanship, and so forth. But this is not the chief or most prominent idea implied in the usual application of the term. If we consult usage, we shall find that genius is more frequently spoken of in connection with the poet, painter, architect, &c., than with the man of science or of practice; as if there was something in the regions of fine art that came more directly home to the susceptibilities of men, and evoked their expressions of admiration and praise. And such is really the case. The artist's function is to touch immediately the chords of human pleasure; the men of practical life, the physician, lawyer, or engineer, have more to do with the deliverance from pains or from obstacles to pleasure, and however necessary their work may be, it is apt to be associated with the dark and gloomy side of our human life.

Undoubtedly, the most important meaning of the term, as pointing to a fundamental peculiarity in which human minds differ, is that connecting it with originality, invention, or creative power, in any department of intellectual activity, artistic, scientific, or practical. Not poetic creativeness alone, but every effort of the inventive faculties of man, by which new and superior combinations and devices are introduced into the world with a view to diminish the pains and add to the pleasures of mankind, may be properly designated 'genius.' Sufficient authority exists for this more extended use of the word, and we may justify it also by the consideration, that there is a common fact in all these different modes of intellectual superiority, while it is further possible that there may be a common foundation for them all in the constitution of the mind. We mark off the 'department of original power from other departments or

as does the intellect, still of positive value and of real importance—namely, the powers of acquiring and reproducing what has been already produced. Amassed learning, extensive acquisitions in science, educated skill in the common arts or in fine art, may exist in a high degree, and may even confer distinction on the individual and serve useful purposes in life, without the accompaniment of originality. The praise implied in the name 'talent' would be conceded to the best examples of acquired power short of the aptitude for invention. This furnishes the most respectable contrast to genius, being itself something admirable and meritorious. A less esteemed contrast is furnished by the crowd of imitators that follow in the wake of any great and original mind, who aim at producing similar effects without the inward spontaneity of the master, and with only the resource of copying his external form and peculiarities. There is a kind of ability amounting to talent in this power of imitation, and literature always contains both good and indifferent examples of it. We are accustomed to speak of poetasters, playwrights, and copyists, among the writers of every literary period. The imitators of Homer in his own time have not survived; but he, as well as every other great genius, may be tracked in subsequent compositions. Spenser's school of poetry makes the largest section of the published poems of the century succeeding him. Pope impressed his style upon last century; and Johnson's balanced prose continued to be reproduced long after his death.

The meaning of genius being thus understood as referring to original creativeness, or inventive power, it has been considered a problem of interest to trace it to its foundations in the mind, with a view to determine whether it be a distinct faculty, or only a superior degree of other recognised powers. Johnson's definition is well known; 'large general powers turned in a particular direction.' This negatives the idea of a specific endowment, and would seem to imply that the man of genius could be anything that he pleased; that Aristotle might have been Pindar, and Homer have discovered the forty-seventh of Euclid; an assumption in the last degree improbable, if not verging on absurdity. There is a class of minds noted for versatility, but they are only a select class. Cæsar was a general, an orator, and a writer, besides being a politician of mark, whether successful or unsuccessful. But, according to the most enlightened theories of the present day, it is usual to consider human beings as born with distinctive endowments; and although there is a common mental organisation at the basis, yet this is supposed to have a plurality of distinct functions, any one of which may rise in degree without the rest. Thus, intellect may be powerful on the whole, without involving a proportionate intensity of the feelings or the volition; the sensibility of the ear may be acute, and that of the eye only average. Now it would be fair to suppose that genius in one line—as, for example, painting—would result from the unusual augmentation of the susceptibilities and powers specially exercised in the art; the sense of colour and of form, skill of hand, and a good recollection of those objects of nature and human life, that are the fitting material of a painter's compositions. So a poet should have a more than common ear for verse, plenty of language, taste for the appropriate images of poetry, and so on. In this way we might, by a kind of analysis, determine which of the faculties common to all men should be exalted to a superior pitch, in order to furnish a genius in each separate walk. This method has been pursued by the phrenologists and by other speculators, and is probably now the received mode

of handling the subject. Examples may be seen in Bain on the *Study of Character*.

GENLIS, STÉPHANIE FÉLICITÉ, COMTESSE DE, was born at Champcéry, near Autun, in Burgundy, 25th January 1746, of an ancient but reduced family. Her maiden name was Ducrest. At the age of 15 she was married to the Comte de Genlis; and in 1770, through the influence of her aunt, Madame de Montesson (who had been privately married to the Duc d'Orléans), was made a lady-in-waiting in the household of the Duchesse de Chartres. In 1782, the Duc de Chartres, afterwards known as Egalité, appointed her 'governor' of his children. This appointment gave rise to certain scandalous reports, the truth of which subsequent circumstances appear to have confirmed. Madame de G. wrote a variety of works for her pupils, among others, *Théâtre à l'usage des jeunes personnes, ou Théâtre d'Education* (Paris, 1779—1780); *Adèle et Théodore, ou Lettres sur l'Education* (1782); and *Les Veillées du Château, ou Cours de Morale, à l'usage des Enfants*. On the breaking out of the Revolution, Madame de G. took the liberal side, but was ultimately compelled to seek refuge in Belgium. Afterwards she went to Switzerland, and in the same year proceeded to Altona, in Germany, where she wrote a romance, entitled *Les Chevaliers du Cygne, ou la Cour de Charlemagne*; and also *Précis de la Conduite de Madame de Genlis pendant la Révolution*, as a sort of reply to the accusations of her numerous enemies. When Bonaparte became consul, she returned to Paris, and received from him a pension. From this time she resided constantly in Paris, publishing in rapid succession one book after another till her death 31st December 1830. Madame de G.'s writings amount to about 90 volumes. They are chiefly descriptions of incidents in fashionable society, with which she was thoroughly acquainted, and which she painted in lively colours. As she advanced in life, her writings became more and more polemical and ill-natured. Her *Observations Critiques pour servir à l'Histoire littéraire du 19me siècle* (2 vols. Paris, 1818); and her *Dictionnaire Critique et raisonné des Etiquettes de la Cour, des usages du Monde, &c.*; and her *Dîners du Baron d'Holbach*, subjected her to severe criticism. The last of these contains a great deal of curious but malicious information concerning the freethinkers of the 18th century. Nevertheless, her writings have been very popular, and have passed through several editions. Her voluminous *Mémoires* were written after she had reached her 80th year.

GENNESARET, SEA OF, called also in the New Testament, *The Sea of Galilee*, and *The Sea of Tiberias* (from the city of Tiberias), and in the Old Testament *The Sea of Chinnereth* or *Cinneroth*, from an ancient town of that name situated on or near its shores. The word G. itself is supposed by some to be merely a corruption of Chinnereth; but others derive it from *Gannah*, a 'garden,' and *Sharon*, the name of a plain, between Mount Tabor and the lake. The Sea, or rather, Lake of G. is about 13 miles long and 6 broad. It lies in the bottom of a great basin, and is undoubtedly of volcanic origin. Although the Jordan runs into it red and turbid from the north, and many warm and brackish springs also find their way thither, its waters are cool, clear, and sweet. Its shores are also enlivened with sparkling pebbles. Now, as formerly, it abounds in fish; but the fisheries are almost entirely neglected. The surrounding scenery is not very beautiful, but its associations are among the most sacred in Palestine. 'Where'er we tread, 'tis haunted, holy ground.' 'Like Jerusalem, the Sea of Gennesaret is enshrined in the

heart from childhood. The home of Christ—"His own city"—Capernaum, lay on its shores; many of His miracles were performed around and upon it; He taught the multitudes that followed Him, on the heights over it, along its pebbly beach, and from a boat on its surface; most of the apostles were fishermen, who here gained their daily bread; and one of Christ's last earthly interviews with them, after the crucifixion, was on that occasion when, driven probably by necessity, they had temporarily resumed their old occupation, and had toiled a long night without success' (Porter, *Handbook for Syria and Palestine*, Part ii. page 418). In the time of Christ, the region round about was the most densely populated in Galilee. Nine cities and towns stood on the shores of the lake, while the neighbouring plains and eminences were dotted with numerous large villages. Of the nine cities, seven are now uninhabited ruins; half-a-dozen mud-hovels are sufficient to house all the human life at Magdala, and only Tiberias continues to exhibit some feeble traces of its former prosperity.

GENOA (Ital. *Genova*; Fr. *Gènes*; anciently, *Genua*), a city of Italy, situated on the Mediterranean Gulf of the same name, at the foot of the Apennines, 79 miles south-east of Turin, is the chief commercial seaport of the Sardinian provinces. Lat. of light-house, 44° 24' 18" N., long. 8° 54' 24" E. The pop. of the town of G. is 119,610; that of the province of which it is the capital, 643,380.

From the sea the aspect of G. is a splendid panorama; the slopes of the hills down to the shore are covered with palaces, churches, hotels, and private dwellings, relieved by terraced gardens and groves of orange and pomegranate trees; while the bleak summits of the loftier ranges are capped with forts, batteries, and outworks, which constitute a line of fortification of great strength and extensive circuit.

The fine harbour, of which the diameter is rather less than a mile, is semicircular, and formed by two piers, at the extremity of one of which stands a light-house tower, 300 feet high. Vessels of the largest class can enter inside the harbour, and, notwithstanding the heavy swells occasioned by south-west winds, the harbour is remarkably safe. As yet, however (1862), there is no landing pier for passengers, all of whom, at considerable inconvenience, are carried ashore a distance of nearly half a mile in row-boats. Subject to this drawback, the harbour is visited daily by French and Italian steamers in communication with other ports in the Mediterranean. It is anticipated that the increase of passenger traffic consequent on the opening of the railway to Turin, which has already given rise to sundry improvements, will cause this defect also to be remedied.

Several important establishments are grouped round the port—viz., the arsenal, the convict prison, the custom-house, and the *Porto Franco* or free-port warehouses, where merchandise may be stored previous to its re-exportation free of duty. G. is the great commercial dépôt of a wide extent of country, of which the chief raw exports are olive oil, rice, fruits, cheese, steel, &c.; the manufactured goods exported are velvets, silks, damask, gloves, flowers, paper, soap, jewellery in silver and coral, in all of which industrial branches the excellence of the Genoese workmen is incontestable. The imports are principally cottons, raw cotton, woollens, cochineal, indigo, grain, hides, &c. The annual exports of G. are valued at £3,000,000, while the imports are returned at £2,000,000.

While strikingly grand as viewed from the sea, and so far worthy of being entitled *La Superba*, a closer examination of G. tends materially to lower

its character for beauty and magnificence. Hewed within walls, and built awkwardly on irregular rising grounds, it has never been opened up by any comprehensive plan of improvement, and remains very much a labyrinth of narrow and intricate lanes, accessible only to foot-passengers, or to the pack-mules, by the use of which a large portion of the internal goods traffic is conducted. These thoroughfares, into which the light of day imperfectly penetrates, are lined with tall buildings, some of them of marble and of handsome architecture, but they can with difficulty be seen from the limitedness of the space in front; and however grand, they consequently fail in effect. Many of them—once the residence of merchant-princes—are now transformed into hotels or business establishments; in some cases, the superb lobbies, environed by marble columns, being occupied by petty traders, and shabby in the extreme. Only a few streets are wide enough for carriages, and in these the aspect of affairs is more like that of modern cities. Fallen from their high estate generally, several *palazzos* still belong to persons of distinction who have the means of maintaining them in their original splendour, or they are appropriated as public buildings. The two most famous are the Palazzo Ducale, formerly inhabited by the doges, now appropriated to the meetings of the senate; and the Palazzo Doria, presented, in 1522, to the great Genoese citizen Andrea Doria, whose residence it was during his presidency of the Republic. The palaces Brignole Sale, Serra, Reale, Pallavicini, Spinola Balbi, Negroni, and many others, possess great interest both on account of their historical fame and architectural beauty. Many of them contain galleries of paintings, which are shewn for a fee. Some of the churches are particularly fine: the most noticeable of all being the cathedral of St Lorenzo, a grand old pile in the Italian Gothic style. G. contains many excellent public institutions, which almost all date from the period of the republic. The great hospital, and the asylum for the poor (*Albergo de' Poveri*), are especially worthy of mention. The latter makes provision for 1600 persons, orphans and old people. The former are trained up to useful employments, and such girls as marry out of the hospital receive a small dowry. The deaf and dumb institution, and the hospital for the insane, are the first in Italy in point of extent and regulation. There are numerous excellent foundations called *conservatorie*, devoted to various philanthropic purposes, the chief of which is called the Fieschine, and is an asylum for female orphans. The public library contains 50,000 volumes, and is unrestrictedly open to the public. The Academy of Fine Arts was founded by the Doria family. The theatres of G. are very fine, that of Carlo Felice ranks among the best in Italy.

The Genoese are a shrewd, active, laborious race, and possess all the qualities of a commercial and maritime community. They make skilful and hardy seamen, energetic traders, and thrifty husbandmen, and are still remarkable for the spirit of enterprise and freedom which so strongly characterised the period of the republic. Claiming Columbus as a native of their city, they are now engaged in rearing a public monument in honour of that distinguished navigator. While the main business of the town is evidently maritime, there is also an extensive trade carried on in the manufacture and sale of a peculiar kind of jewellery. This consists of remarkably fine filigree-work in silver and silver gilt, which resembles that of India, and is fully as precious in point of intrinsic value. Few of the many tourists who pass through G. fail to purchase one or more of these pretty and cheap articles of bijouterie.

History.—The early history of G. and of its ancient inhabitants is full of uncertainty, owing to the fabulous traditions by which it is obscured. The Ligurian tribes, who held possession of G. previous to its incorporation with ancient Rome, are of disputed origin. By some historians, they are classed with the Celtic race, while others hold them to be of Greek extraction. G. is first mentioned in history during the Second Punic War, but it then appears to have been a place of considerable importance. In 205 B.C., it became for a short time the head-quarters of Mago, the Carthaginian general, who destroyed it before leaving the country; but in 203 B.C., the Roman prætor, Sp. Lucretius, was commissioned to rebuild it. After Liguria was conquered by the Romans (109 B.C.), G. does not figure much in ancient history; but as a Roman *municipium*, it obviously prospered, for Strabo speaks of it as a 'flourishing town, and the chief emporium of the Ligurians.' Under the Romans, the Genoese retained a considerable degree of internal independence, and were distinguished in the Roman legions by their valour and great physical vigour. On the dismemberment of the Latin empire, G., in common with the chief divisions of Italy, successively fell under the sway of the Lombards, the Franks, and the Germans; but amid all these vicissitudes, preserved, in a singular degree, both privileges and prosperity. Navigation and commerce were the two natural sources opened to the Genoese by the maritime situation of their country, and for these pursuits they have at all times displayed a special aptitude. Their mercantile interests only served to foster the instinctive valour of the race. The rich merchandise of the Genoese galleys offered an alluring prize to the piratical hordes by which the Mediterranean was universally infested; and, consequently, from the rise of their commercial importance, the Genoese were compelled to defend with the sword the precious freight of their merchantmen. Unhappily, a bitter spirit of hostility and intolerance of all maritime competition was a leading feature of early Genoese policy, in regard to the other important Italian states; and to this source may be traced the fierce and prolonged wars sustained by G. against the rival maritime republics of Pisa and Venice. The frequent incursions of the Saracens, by whom G. was sacked and pillaged about 935, led the Genoese to form an alliance with Pisa, with the object of extirpating these barbarous aggressors from the islands of Corsica and Sardinia, their strongholds in the Mediterranean. This being effected (1016–1021), the Genoese obtained, by papal arbitration, the grant of Corsica, while Sardinia was assigned to the Pisans, a distribution which sowed the seeds of future discord between the two states. At the close of the 11th c., G. commanded large land and naval forces, and already ranked as a powerful maritime state, governed by annual magistrates, named consuls. The Genoese vigorously seconded the Crusades, and in return for their effective co-operation, obtained several important maritime possessions and commercial privileges in the Holy Land (1109). The chief events of the three following centuries are: the capture of Minorca (1146), of Almeria (1147), and Tortosa (1148) from the Moors; the wars with Pisa and Venice, and the civil dissensions by which G., in common with all Italy, became distracted by the Guelph and Ghibelline factions. In 1284, at the great naval battle of Meloria, the Pisan republic sustained such destructive losses, that her maritime influence and public spirit never revived. The wars with Venice originated, about 1244, in mutual jealousies respecting the commercial supremacy of

the Levant, and continued, with various vicissitudes, till the end of the following century, when the Genoese, at the blockade of Chiozza, were compelled to submit to disadvantageous terms by the peace of Turin (1381).

Co-existent with these suicidal wars, the civil dissensions of G. exhausted and demoralised the state, and occasioned an infinity of changes in the primitive form of government. In 1190, the consuls were superseded by a magistracy termed *podesta*, an office for which natives of G. were declared ineligible. This institution, which was founded in the hope of restraining local Genoese animosities and ambitions, lasted till 1270, when two of the great Guelph leaders of the state resolved to subvert the popular authorities, and, under the title of 'captains of liberty,' assumed irresponsible authority, which, for 21 years, they contrived to retain. During their sway, civil feuds raged inveterately, not alone between the Guelph and Ghibelline factions, but also between the citizen ranks of patricians and plebeians. Various other modifications of the government preceded the election of the first Genoese doge in 1339. This supreme magisterial office, from which all nobles were excluded, continued in force for two centuries, its tenure being for life.

The ambitious contentions of four leading democratic families—viz., the Adorni, the Fregosi, the Guarci, and the Montaldi—succeeded those of the patrician houses of Doria, Spinola, Grimaldi, and Fieschi, and engendered such disastrous civil strife in the state under the early doges, that, in 1396, the citizens, in despair, invoked the protection of the French king, Charles VI., and finally submitted to the rule of the Visconti, the tyrannical and ambitious lords of Milan (1404). After the invasion of Louis XII. in 1499, G. long remained subject to the French; but in 1528, the genius and resolution of a great citizen, Andrea Doria, freed his country from foreign invaders, and restored to G. her republican institutions. The last important exploit of the Genoese was the expulsion, in 1746, of the Austrians, who were driven from G. after an occupation of three months. In 1768, G. ceded to France the Island of Corsica; and in 1796 Bonaparte invaded Italy, and conferred on G. the name of the *Ligurian Republic*, which, in 1802, was abolished, and *Genoa la Superba* became the chief town of a department of France. In 1815, by a decree of the Congress of Vienna, the state of G. became a province of Piedmont. Following the fortunes of that state, it has latterly become a portion of the kingdom of Italy, and with the enterprise of its people there are marked indications of improvement. Canale's *Nuova Storia della Repubblica di Genova*; Dinena's *Rivoluzioni d'Italia*; Sismondi's *Italian Republics*.

GENOA, GULF OF, a large indentation in the northern shore of the Mediterranean, north of Corsica, may be said to have the shape of a bay rather than that of a gulf. The towns of Oneglia on the west, and Spezia on the east, seem to indicate the points at which the entrance of the gulf commences. With this entrance the Gulf of G. would extend 90 miles across, and 30 miles inland.

GENOUILLÈRE, a term in Fortification (q. v.) for that part of the parapet of a battery which lies under the embrasure. The name is derived from Fr. *genou*, knee, as representing the ordinary height of the genouillère above the platform on which the gun is worked.

GENRE-PAINTING, a term derived from the French *genre* ('kind,' 'sort'), originally employed

to distinguish any special branch of painting, as *genre historique* (historic painting), *genre du paysage* (landscape-painting), &c. In a more definite sense it is used to describe any picture containing human figures not included in the so-called historical class, particularly pictures with figures much below the size of life—cattle, architectural pieces, flower-pieces, and representations of still life. Under the term *genre-pictures* are comprehended all pictures with figures representing individuals only as types of a species or class, in contradistinction to historical compositions, which bring before us certain individuals, or, as it were, *nomina propria*. The mode of conception and style of execution in *genre-painting* may resemble the historical style; and, on the other hand, historical personages may be represented merely in situations of everyday life. The term *historic-genre* is employed in both cases. The French likewise distinguish the *genre-historique* from the lower genre, strictly so called; they also occasionally apply the term *peinture du style* to historical painting. *Genre pictures* are usually of limited dimensions, while in historical pictures the figures are commonly the size of life, or even colossal. In either case, however, there are many exceptions to the general rule, and the proper designation depends rather on the style of subject than on the size. A species of *genre-painting* with a distinct style was practised even in ancient times, but the birthplace of the present *genre picture* is the north, and more particularly the Netherlands. The Italians, especially Paul Veronese, had previously shewed a leaning to the *genre style* in biblico-historical pictures, by making the principal figures and the action subordinate to the accessories and locality—as, for example, in his 'Marriage at Cana;' and Van Eyck's school in the Netherlands had likewise introduced the same element into the delineation of incidents in sacred history. Lucas van Leyden and Albert Dürer then began to represent actual scenes from the everyday life of the people in paintings and engravings. *Genre-painting* was brought to its highest perfection in the Netherlands by a series of admirable painters, such as Terburg, Brower, Ostade, Rembrandt, the younger Teniers, Metz, Gerard Dow, and others. Though the characteristic and humorous conception of many of the works of these masters gives them a peculiar value, it was found in other cases that a certain delicacy of imitation and skill in using the brush was capable of imparting a singular charm to the most ordinary scenes and figures. In the British school this style of art is generally understood to be limited to pictures with figures, and many works of the highest excellence have been produced in it, elevated in treatment by the introduction of an important element—viz., the dramatic.

GENS (allied to Lat. *genus*, Eng. *kin*; from the root *gen-*, to beget or produce). This Latin word, to which so many important political and social meanings came to be attached, signifies, properly, a race or lineage. From it our own words Gentleman (q. v.), Gentility, &c., have come to us through the French *gentilhomme*, the primary meaning of which was, one who belonged to a known and recognised stock. By the Romans it was sometimes used to designate a whole community, the members of which were not necessarily connected by any known ties of blood, though some such connection was probably always taken for granted. In this sense we hear of the *gens Latini-orum*, *campanorum*, &c. But it had a far more definite meaning than this in the constitutional law of Rome. According to Scævola, the Pontifex, those alone belonged to the same *gens*, or were

'Gentiles,' who satisfied the four following conditions—viz., 1. Who bore the same name; 2. Who were born of freemen; 3. Who had no slave amongst their ancestors; and 4. Who had suffered no *Capitis Diminutio* (reduction from a superior to an inferior condition), of which there were three degrees, *Maxima*, *Media*, *Minima*. The first (*Maxima Capitis Diminutio*) consisted in the reduction of a free man to the condition of a slave, and was undergone by those who refused or neglected to be registered at the census, who had been condemned to ignominious punishments, who refused to perform military service, or who had been taken prisoners by the enemy, though those of the last class, on recovering their liberty, could be reinstated in their rights of citizenship. The second degree (*Media Capitis Diminutio*) consisted in the reduction of a citizen to the condition of an alien (*Latine* or *peregrinus*), and involved, in the case of a *Latinus*, the loss of the right of legal marriage (*connubium*), but not of acquiring property (*commercium*); and in the case of the *peregrinus*, the loss of both. The third degree (*Minima Capitis Diminutio*) consisted in the change of condition of a *paterfamilias* into that of a *filius familias*, either by adoption (*adrogatio*) or by legitimation. In the identity of name, some sort of approach to a common origin seems to be here implied. The gens thus consisted of many families, but all these families were supposed to be more or less nearly allied by blood—to be, as we should say, kindred. A Roman gens was thus something very nearly identical with a Celtic clan, the identity or similarity of name being always supposed to have arisen from relationship, and not from similarity of occupation, as in the case of the Smiths, Taylors, Lormers, &c., of modern Europe. There was this peculiarity, however, about the gens which did not belong to the clan—viz., that it was possible for an individual born in it to cease to belong to it by *capitis diminutio*, or by adoption, or adrogation as it was called when the person adopted was *Sui Juris* (q. v.). If the adoption was by a family of the same gens, the gentile name, of course, remained unchanged. In the case of a person dying intestate, his gentiles, failing nearer relatives, were his heirs, and they undertook the duties of guardianship in the like circumstances. The gens was further bound together by certain sacred rites, which were imposed on the whole of its members, and for the celebration of which it probably possessed, in common property, a *acellum* or sacred spot enclosed, and containing an altar and the statue of the god to whom it was dedicated. According to the traditional accounts of the old Roman constitution, the gentes were a subdivision of the curiæ, as the curiæ were subdivisions of the tribe. In this view of the matter, the original idea of the gens becomes simply that of the smallest political division, without any relation to kindred or other ties.—An excellent article on the gens by Mr George Long, in which references to the principal German authorities on the subject are given, will be found in Smith's *Dictionary of Roman Antiquities*.

GENSERIC, king of the Vandals, was an illegitimate son of Godigiselus, who led the Vandals into Spain. After the death of his brother Gonderic, G. became sole ruler. In the year 429, he invaded Africa on the invitation of Count Boniface, the viceroy of Valentinian III., Emperor of the West, who had been goaded on to rebellion through the machinations of his rival Aetius, the conqueror of Attila. G.'s army at first amounted to 50,000 warriors, full of barbarian valour, and hungry for conquest and plunder. As they swept along through Mauritania, the Kabyle mountaineers,

and the Donatist heretics, maddened by persecution and fanaticism, swelled the terrible hordes, and more than equalled their savage associates in acts of cruelty and bloodthirstiness. The friends of Boniface, astonished that the hero who alone had maintained the cause of the emperor and his mother Placidia during their exile and distress, should have been guilty of such a crime, attempted, with ultimate success, to bring about an interview between the Count of Africa and an agent of the empress. Then, when too late, were the imaginary provocations he had received explained, and the fraud of Aetius detected, for the army he had hurriedly collected to oppose the Vandals, having been twice defeated by G., he was compelled to retire to Italy, where he was soon afterwards slain by Aetius. All Africa west of Carthage fell into the hands of G., who shortly after seized that city itself, and made it (439 A. D.) the capital of his new dominions. Part of Sicily, Sardinia, and Corsica was likewise taken possession of by him. In the year 451, he encouraged Attila to undertake his great but fatal expedition against Gaul. Tradition states that, at the request of Eudoxia, the widow of Valentinian, who was eager for revenge upon her husband's murderer Maximus, G., in the year 455, marched against Rome, which he took, and abandoned to his soldiers for 14 days. On leaving the city, he carried with him the empress and her two daughters, one of whom became the wife of his son Huneric. The empire twice endeavoured to avenge the indignities it had suffered, but without success. First the Western emperor, Majorian, fitted out a fleet against the Vandals in 457, which was destroyed by G. in the bay of Carthage; second, the Eastern emperor, Leo, sent an expedition under the command of Heraclius and others in 468, which was also destroyed off the city of Bona. G. died in 477, in the possession of all his conquests, leaving behind him the reputation of being the greatest of the Vandal kings. His appearance was not imposing: according to Jornandes, he was 'of low stature, and lame on account of a fall from his horse,' but 'deep in his designs, taciturn, averse to pleasure, capable of being transported into fury, greedy of conquest, and cunning in sowing the seeds of discord among nations, and exciting them against each other.' Strange to say, a rude, even a savage religiosity burned in the heart of G., and, it may be, grimly sanctified, in his own eyes, his wide-spread devastations. He seems to have regarded himself as a 'scourge of God.' Once when leaving the harbour of Carthage on an expedition, the pilot asked him whither he was going. 'Against all who have incurred the wrath of God.' In creed, G. was a fierce Arian, and inflicted the severest persecutions upon the orthodox or Catholic party.

GENTIAN (*Gentiana*), a genus of plants of the natural order *Gentianaceae*, with 5-cleft—sometimes 4-cleft—calyx, and 1-celled capsule. The species are numerous, natives of temperate parts of Europe, Asia, and America, many of them growing in high mountain pastures and meadows, which they adorn by their beautiful blue or yellow flowers.—The genus is said to derive its name from Gentius, king of Illyria, who was vanquished by the Romans about 160 B. C., and to whom is ascribed the introduction into use of the species still chiefly used in medicine. This species, **COMMON G.**, or **YELLOW G.** (*G. lutea*), is abundant in the meadows of the Alps and Pyrenees, at an elevation of 3000–6000 feet. It has a stem about three feet high, ovate-oblong leaves, and numerous whorls of yellow flowers. The part employed in medicine is the root, which is cylindrical, ringed, and more or

less branched; and which appears in commerce in a dried state, in pieces varying from a few inches to more than a foot in length, and from half an inch to two inches in thickness. It is collected by the peasants of the Alps. Although

Common Gentian :

a, capsule; b, capsule cut across; c, vertical section of seed, magnified.

G. root has been examined by various chemists, its constituents are not very clearly known; it contains, however (1), an oil in small quantity; (2), a pale yellow crystalline matter, termed gentian or gentinic acid; (3), a bitter principle, gentianite, on which its medicinal properties mainly depend; (4), pectin or pectic acid, which probably causes the gelatinisation that sometimes occurs in infusion of G.; and (5), sugar, in consequence of which an infusion is capable of undergoing vinous fermentation, and of forming the 'bitter snaps' or 'engianceist' which is much employed by the peasants on the Swiss Alps, to fortify the system against fogs and damp. (As 'bitter snaps' contains a narcotic principle, due probably to the oil of G., strangers unaccustomed to its use should take it with caution.) G. is a highly valued medicine, a simple tonic bitter without astringency, and is much used in diseases of the digestive organs, and sometimes as an anthelmintic.

G. may be administered in the form of infusion, tincture, or extract. The *Compound Mixture of G.* of the London Pharmacopoeia, consisting of six parts of compound infusion of G. (Ph. L.), three parts of compound infusion of senna (popularly known as *Black Draught*), and one part of compound tincture of cardamoms, forms, in doses of from one to two ounces, a safe and moderately agreeable tonic and purgative medicine in cases of dyspepsia with constipation. An imitation of the *Compound Tincture of G.*, known as *Stoughton's Elixir*, is very much used in the West Indies before meals as a pleasant bitter, to give tone to the languid stomach. The *Extract of G.* is very commonly used as the vehicle for the exhibition of metallic substances (such as salts of iron, zinc, &c.) in the form of pill. *Powdered G.* is one of the chief constituents of an empirical medicine known as *The Duke of Portland's Gout Powder*. The bitter principle on which its virtue depends exists also in other species of this genus, probably in all, and appears to be common to many plants of the same order. The roots of *G. purpurea*, *G. pancha*,

and *G. Pannonica*, are often mixed with the gentian of commerce. They are deemed inferior. Several species are natives of Britain, but none are at all common except *G. campestris* and *G. amarella*, plants of a few inches in height, with small flowers, both of which are in use as tonics, although only in domestic medicine.—*G. Catesbaei*, a North American species, is extensively used in its native country, as a substitute for Common G., and *G. Kurroo* is employed in the same way in the Himalaya.—Several species of *G.* are common ornaments of our gardens, particularly *G. acaulis*, a small species with large blue flowers, a native of the continent of Europe and of Siberia, often planted as an edging for flower-borders. Of North American species, *G. crinita* is particularly celebrated for the beauty of its flowers, which are large, blue, and fringed on the margin. It has a branched stem, and grows in wet ground. The brilliancy of the flowers of the small alpine species has led to many attempts to cultivate them, which have generally proved unsuccessful, apparently from the difficulty of imitating the climate and seasons of their native heights.

GENTIANACEÆ, or **GENTIANEÆ**, a natural order of exogenous plants, consisting chiefly of herbaceous plants, but containing also a few small shrubs. The leaves are opposite, rarely alternate, destitute of stipules. The flowers are terminal or axillary, generally regular. The calyx is divided usually into 5, sometimes into 4, 6, 8, or 10 lobes; the corolla is hypogynous (q. v.), has the same number of divisions with the calyx, and a plaited or imbricated twisted aestivation. The stamens are inserted upon the corolla, alternate with its segments, and equal to them in number. The ovary is composed of two carpels, 1-celled or imperfectly 2-celled, many-seeded. The fruit is a capsule or berry.—The species are numerous, about 450 being known. They are natives both of warm and cold climates, but rather of elevated regions in the torrid and temperate zones, than of cold regions near the poles. Many have flowers of great beauty, both of colour and form, the corolla being often most delicately fringed. Many are medicinal, as **GENTIAN**, **CHIRATA**, **FRASERA**, **BUCKBEAN**, and **CENTAURY**. See these headings.

GENTIANELLA, a name sometimes given to the small-flowered or autumnal Gentian (*Gentiana Amarella*), the beautiful blue flowers of which adorn some of the dry pastures of Britain; but more commonly to the species of *Cicendia*, another genus of the order *Gentianaceæ*, of which one (*C. filiformis*, formerly *Exacum filiforme*) is a native of Britain, growing in sandy peat-soils, chiefly in the south-west of England—a small, slender, and graceful plant with yellow flowers. *C. hyssopifolium* is much employed as a stomachic in India.

GENTILLY, a populous village of France, in the metropolitan department of Seine, is situated near Paris, towards the south of that city. The great bastioned wall of Paris passes through the village, separating it into two portions, called Great and Little Gentilly. Pop. 15,000, who are employed in the manufacture of chemicals, in quarrying, and in washing.

GENTLEMAN. This word is an example of those compromises so frequent in English between the language introduced by the Normans, and that in possession of the country at the period of the Conquest. The Norman word was, as the French word is now, *gentilhomme*. The first syllable was retained, whilst the second was abandoned in favour of its Saxon equivalent, *man*. Though commonly translated into Latin by *GENEROUS*, which means a generous, liberal, manly person, in short, a gentle-

man, the word gentleman is derived from *gentilis*, and *homo*, or man; and *gentilis* in Latin did not signify gentle, generous, or anything equivalent, but *belonging to a gens*, or known family or clan. See **GENS**. A gentleman was thus originally a person whose kindred was known and acknowledged; which is the sense in which it is still employed when it is not intended to make any reference to the moral or social qualities of the particular individual. One who was *sine gente*, on the other hand, was one whom no *gens* acknowledged, and who might thus be said to be ignobly born.

The term gentleman is continually confounded with Esquire (q. v.), even by such learned authorities as Sir Edward Coke. But they are not equivalent; and whilst some attempt can be made to define the latter, the former seems in England, from a very early time, to have been a mere social epithet. 'Ordinarily, the king,' says Sir Thomas Smith, 'doth only make knights and create barons, or higher degrees; as for gentlemen, they be made good cheap in this kingdom; for whosoever studieth the laws of the realm, who studieth in the universities, who professeth the liberal sciences, and (to be short) who can live idly, and without manual labour, and will bear the port, charge, and countenance of a gentleman, he shall be called Master, for that is the title which men give to esquires and other gentlemen, and shall be taken for a gentleman.'—*Commonwealth of England*, i. c. 20. But though such was the real state of matters, even in the beginning of the 17th c., the word was still held to have a stricter meaning, in which it was more nearly synonymous with the French *gentilhomme*, for in the same chapter the same writer remarks that 'gentlemen be those whom their blood and race doth make noble and known.' Even here, however, it scarcely seems that he considered any connection with a titled family to be necessary to confer the character, for he afterwards speaks of it as corresponding not to nobility, in the English sense, but to *nobilitas*, in the Roman sense, and as resting on 'old riches or powers remaining in one stock.' There can be no doubt that, in still earlier times, patents of gentility were granted by the kings of England. There is one still in existence by Richard II. to John de Kingston, and another by Henry VI. to Bernard Angevin, a Bourdelois. But these patents determine very little, for they seem to have carried the rank and title of esquire; and there is no doubt that esquires, and all persons of higher rank, were held to be gentlemen, on the principle that the greater includes the less. The difficulty is to say whether between an esquire, who certainly was entitled to the character, and a yeoman, who was not, there was an intermediate class who could claim it on any other grounds than courtesy and social usage. These patents corresponded to the modern patents of arms which are issued by the Heralds' Colleges in England and Ireland, and by the Lyon Office in Scotland, and were probably given on the very same grounds—viz., the payment of fees. A patent of arms confers the rank of esquire, and there probably is no other legal mode by which an untitled person can acquire it, unless he be the holder of a dignified office. In present, as in former times, it is common to distinguish between a gentleman by birth and a gentleman by profession and social recognition. By a gentleman born is usually understood either the son of a gentleman by birth, or the grandson of a gentleman by position; but the phrase is loosely applied to all persons who have not themselves 'risen from the ranks.'

GENTLEMAN-COMMONER. See **UNIVERSITY**, **OXFORD**, &c.

GENTLEMEN-AT-ARMS (formerly called the **GENTLEMEN-PENSIONERS**), the body-guard of the British sovereign, and, with the exception of the yeomen of the guard, the oldest corps in the British service. It was instituted in 1509 by Henry VIII., and now consists of 1 captain, who receives £1000 a year; 1 lieutenant, £500; 1 standard-bearer, £310; 1 clerk of the cheque, £120; and 40 gentlemen, each with £70 a year. The pay is issued from the privy purse. Until 1861, the commissions were purchasable, as in other regiments; but by a royal command of that year purchase has been abolished in the corps, and, henceforth, the commissions as gentlemen-at-arms are to be given only to military officers of service and distinction. The attendance of the gentlemen-at-arms is now rarely required, except on the occasions of drawing-rooms, levees, coronations, and similar important state ceremonies. The appointment, which is in the sole gift of the crown, on the recommendation of the commander-in-chief, can be held in conjunction with half-pay or retired full-pay, but not simultaneously with any appointment which might involve absence at the time of the officer's services being required by the sovereign.

GENTOO (Portuguese, *Gentio*, 'Gentile') was the term applied by old English writers to the natives of Hindustan; it is now entirely obsolete, the word Hindoo, or properly Hindu, having been substituted.

GENUFLEXION, the act of kneeling or bending the knees in worship. As an act of adoration, or reverence, there are frequent allusions to genuflection in the Old and in the New Testament: as Gen. xvii. 3 and 17; Numbers xvi. 22; Luke xxii. 41; Acts vii. 60, and ix. 40; Philip. ii. 10. That the use continued among the early Christians is plain from the *Shepherd of Hermas*, from Eusebius's *History*, ii. 33, and from numberless other authorities; and especially from the solemn proclamation made by the deacon to the people in all the liturgies—'Flectamus genua' (Let us bend our knees); whereupon the people knelt, till, at the close of the prayer, they received a corresponding summons—'Levate' (Arise). It is worthy of remark, however, that in celebration of the up-rising (resurrection) of our Lord, the practice of kneeling down at prayer, so early as the age of Tertullian, was discontinued throughout the Easter-time, and on all Sundays through the year. The kneeling posture was especially assigned as the attitude of penance, and one of the classes of public penitents in the early church took their name, *genuflectentes*, from this circumstance. In the modern Roman Catholic Church, the act of genuflection belongs to the highest form of worship, and is frequently employed during the mass, and in the presence of the consecrated elements when reserved for subsequent communion. In the Anglican Church, the rubric prescribes the kneeling posture in many parts of the service; and this, as well as the practice of bowing the head at the name of Jesus, was the subject of much controversy with the Puritans. The same controversy was recently revived in Germany.

GENUS (Lat. a kind), in Natural History, a group of species (q. v.), closely connected by common characters or natural affinity. See **GENERALISATION**. In all branches of zoology and botany, the name of the genus forms the first part of the scientific name of each species, and is followed by a second word—either an adjective or substantive—which distinguishes the particular species. Thus, in *Solanum tuberosum* (the potato), *Solanum* is the generic, and *tuberosum* the specific (sometimes styled the *trivial*) name. This method was introduced by Linnaeus, and has been of great advantage to the

progress of science, simplifying the nomenclature, and making names serve, in some measure, for the indication of affinities. The affinities indicated by the generic name are often recognised even in popular nomenclature—thus, *Elm* and *Ulmus* are perfectly synonymous; but there are many instances in which this is very far from being the case, as that of the genus *Solanum*. The arrangement of species in groups called genera has no real relation to any of the important questions concerning species.—Genera are arranged in larger groups called *orders*, which are often variously subdivided into *sub-orders*, *families*, *tribes*, &c.; and are themselves grouped together in *classes*, which are referred to *divisions* of one or other of the *kingdoms* of nature. Some genera contain hundreds of species; others no more than one; and although future discoveries may add to the number in many of the smallest genera, yet it cannot be doubted that a very great difference exists in the number actually belonging to groups equally distinct and natural. Some of the larger genera are, by some authors, divided into sub-genera; and too many naturalists shew an extreme anxiety to multiply generic divisions and names, perhaps forgetting that whilst certain affinities may be thus indicated, the indication of others is necessarily lost, whilst the memory of every student of science is more and more heavily burdened. There can be no doubt, however, that to a certain extent the fluctuations of nomenclature, so often felt to be annoying, mark the progress of science and the removal of errors.

In Mineralogy, the generic name is not adopted as the primary part of the name of each species. *Gem* (q. v.) is an example of a mineralogical genus.

GEOCENTRIC means, having the earth for centre; thus the moon's motions are geocentric; also, though no other of the heavenly bodies revolves round the earth, yet their motions are spoken of as geocentric when referred to, or considered as they appear from, the earth.

The geocentric latitude of a planet is the inclination to the plane of the ecliptic of a line connecting it and the earth; the geocentric longitude being the distance measured on the ecliptic from the first point of Aries of the point in the ecliptic to which the planet as seen from the earth is referred.

GEODES (Gr. *earthly*) are rounded hollow concretions, or indurated nodules, either empty or containing a more or less solid and free nucleus, and having the cavity frequently lined with crystals. They are sometimes called 'potato stones,' on account of their size and shape. The name *geode* seems to have been given them because they are occasionally found filled with a soft earthy ochre.

GEODESY, the science of the measurement of the earth's surface, and of great portions of it. The reader will find under **EARTH** the principal results of geodetical measurements, and under **TRIANGULATION**, an account of some of the methods of obtaining them. Geodesy has many physical difficulties to contend against. In measuring a particular length with a view to obtaining a base line for calculating other lines by trigonometrical observations, there is first a difficulty arising in the use of the unit of length, whatever it may be, whether rod or chain. In the use of rods, it is difficult to lay them all precisely in the same direction, and to prevent error arising from intervals between the rods. In the use of chains, again, the greatest care is needed to keep all the links stretched, while the difficulty of avoiding error through not preserving the line of direction is but little diminished. Further, in all cases, the tendency of the units to change magnitude with changes of temperature, and the unevenness of the

earth's surface, are pregnant sources of error. After all these difficulties have been overcome, and a sufficient base line obtained, a new class of difficulties are encountered. In taking trigonometrical observations of distant objects, it is found that the three angles of any triangle which we may form are together in excess of two right angles; the angles are, in fact, more of the nature of spherical than plane angles. For this, in using the angles as plane angles (for greater simplicity), a correction has to be made. Further, a correction is required for the effect of horizontal refraction on the results of observations on distant objects—a most fluctuating source of error—to evade which, as far as possible, it is usual to make observations when the atmosphere has been for some time undisturbed. See Puissant's work on Geodesy.

GEOFFREY OF MONMOUTH, called also **JEFFREY AP ARTHUR**, was born at Monmouth, and in 1152 was consecrated Bishop of St Asaph. He died about 1154. His chief work, the *Chronicon sive Historia Britonum*, seems to have been completed about 1128. It is a tissue of the wildest fables, interwoven with some historic traditions. 'In later times,' says Dr Lappenberg, 'authors seem to have unanimously agreed in an unqualified rejection of the entire work, and have therefore failed to observe that many of his accounts are supported by narratives to be found in writers wholly unconnected with, and independent of Geoffrey. He professes to have merely translated his work from a chronicle in the British tongue, called *Brut y Brenhined*, or History of the Kings of Britain, found in Brittany, and communicated to him by Walter, Archdeacon of Oxford [not, as has been supposed, Walter Mapes, but an earlier Walter Calenius]. The *Brut* of Tyssilio has, with some probability, been regarded as the original of G.'s work, though it is doubtful whether it may not itself be rather an extract from Geoffrey. That the whole is not a translation appears from passages interpolated, in many places verbatim, from the existing work of Gildus, of whom he cites another work, *De Vita Ambrosii*, no longer extant.' G.'s work was first printed by Ascensius at Paris in 1508, and has been reprinted more than once. An English translation, by Aaron Thompson, appeared at London in 1718, reprinted by Dr Giles in 1842, and in Bohn's Antiquarian Library, 1848. Whatever its value as a historical record, the Chronicle has been of great use to our literature. Versified in the Norman dialect by Wace, and again in English by Layamon, we are indebted to it for the story of Lord Sackville's tragedy of *Ferrex and Porrex*, for Shakespeare's *King Lear*, for some of the finest episodes in Drayton's *Polyolbion*, and for the exquisite fiction of Sabrina in Milton's masque of *Comus*. A metrical *Life and Prophecies of Merlin*, first printed at Frankfurt in 1603, and reprinted for the Roxburghe Club in 1830, has been attributed to Geoffrey of Monmouth, but without sufficient grounds.

GEOFFFRIN, MARIE THÉRÈSE, a distinguished Frenchwoman, born at Paris, 2d June 1699. She was the daughter of a valet-de-chambre named Rodet, a native of Dauphiné; and in her fifteenth year was married to a very rich manufacturer in the Faubourg St Antoine, who died not long after, leaving her an immense fortune. Madame G., though but imperfectly educated herself, had a genuine love of learning, and her house soon became a rendezvous of the philosophers and *littérateurs* of Paris. No illustrious foreigner visited the city without obtaining an introduction to her circle; even crowned heads were among her visitors. Her liberality to

men of letters, and especially the delicacy with which she conferred her benefits, reflect the highest credit on her character. Among those who frequented her house was Poniatowski, afterwards king of Poland. He announced to her his elevation to the throne in these words: '*Maman, votre fils est roi*.' In 1766, he prevailed on her to visit Warsaw where she was received with the greatest distinction. Subsequently, in Vienna, the Empress Maria Theresa and her son, Joseph II., honoured her with a most gracious reception. She died in October 1777, leaving legacies to most of her friends. Towards the publication of the *Encyclopédie* she contributed, according to the calculations of her daughter, more than 100,000 francs. D'Alembert, Thomas, and Morellet, wrote éloges upon her, which are to be found in the *Éloges de Madame Geoffrin* (Paris, 1812). Morellet likewise published her treatise *Sur la Conversation*, and her *Lettres*.

GEOFFROY SAINT-HILAIRE, ETIENNE, a French zoologist and physiologist, was born at Etampes in 1772, and died at Paris in 1844. He was destined by his family for the clerical profession, and was sent to prosecute his studies at the College of Navarre, where he attended the lectures of Brisson, who speedily awakened in him a taste for the natural sciences. He subsequently became a pupil of Hatty (q. v.) and of Daubenton; and the relations which were soon established between his masters and himself were attended with the happiest results to science, since they decided the future prospects of G., and saved the life of Hatty, who had been imprisoned as a refractory priest, and whom G. rescued from prison on the very eve of the massacres of September 1792. A few months afterwards, Hatty obtained for him the post of sub-keeper and assistant-demonstrator at the Jardin des Plantes; and in June 1793, on the reorganisation of the institution, he was nominated professor of the zoology of vertebrated animals. At first, he refused to accept the chair, on the ground that all his studies had been directed to mineralogy; but he finally yielded to the urgent persuasion of his old master Daubenton, and at once set resolutely to work. At this time, he was only 21 years of age.

Immediately after his installation, he commenced the foundation of the menagerie at the Jardin des Plantes, its beginning being three itinerant collections of animals that had been confiscated by the police, and were conveyed to the museum. All the departments of the museum over which he had charge soon exhibited signs of his vigorous administration; and the zoological collection became the richest in the world.

In 1795, G. having heard from the Abbé Tessier that he had found a young man in the wilds of Normandy who was devoting all his leisure time to natural history, and having subsequently received from the stranger a communication containing some account of his investigations, wrote thus to his unknown correspondent: 'Come to Paris without delay; come and assume the place of a new Linnæus, and become another founder of natural history.' It was thus that Georges Cuvier was called to Paris by the prophetic summons of Geoffroy. An intimate friendship was soon established between them, which, although long afterwards broken by the asperity of scientific discussion, was finally revived, with all its original warmth in their later days.

In 1798, G. formed one of the scientific commission that accompanied Bonaparte to Egypt, and he remained in that country until the surrender of Alexandria in 1801. He succeeded in bringing to France valuable collections of natural history specimens; and the Memoirs in which he described them led to his election, in 1807, into the Academy

of Sciences. In 1808, he was charged with a scientific mission to Portugal, the object of which was to obtain from the collections in that kingdom all the specimens which were wanting in those of France. On his return, he was appointed to the professorship of zoology in the Faculty of Science at Paris, and from that time he undertook no more expeditions, but devoted himself almost exclusively to science. In the latter years of his life, he was stricken with total blindness, but the physical repose to which he was consequently condemned, seemed to increase his intellectual activity; and to the very last days of his life, he was occupied with those abstruse questions of biology which had influenced his whole scientific career. Throughout almost all his writings, we find him endeavouring to establish one great proposition—namely, the unity of the organic plan of the animal kingdom. This was the point on which he and Cuvier mainly differed, and on which there were very warm discussions between these two eminent naturalists in the Academy of Sciences in 1830. In addition to numerous memoirs in various scientific periodicals, he published various works, amongst which we may mention his *Philosophie Anatomique* (2 vols. 1818—1820), which contains the exposition of his theory; *Principes de la Philosophie Zoologique* (1830), which gives a synopsis of his discussions with Cuvier; *Études Progressives d'un Naturaliste* (1835); *Notions de Philosophie Naturelle* (1838); and (in conjunction with Frédéric Cuvier), *Histoire Naturelle des Mammifères* (3 vols. folio, 1820—1842). His son has published an excellent history of his life and labours, under the title, *Vie, Travaux, et Doctrine Scientifique d'E. Geoffroy Saint-Hilaire* (1848), to which, as well as to *L'Eloge Historique de Geoffroy Saint-Hilaire* by Flourens, we are indebted for many of the details contained in this sketch. We may also refer to a very able sketch of the life and doctrines of this great naturalist, in the Appendix to De Quatrefages's *Rambles of a Naturalist*, vol. i. pp. 312—324.

GEOFFROY SAINT-HILAIRE, ISIDORE, a French physiologist and naturalist, son of Etienne Geoffroy, was born in Paris in 1805, and died in that city in 1861. Educated in natural history by his father, he became assistant naturalist at the museum when only 19 years of age, and in 1830 he delivered the zoological lectures in that institution as his father's substitute. The science of Teratology (q. v.), or of the laws which regulate the development of monstrosities, which had occupied much of his father's attention, was taken up with great zeal by the son, and in 1832 he published the first volume of his *Histoire Générale et Particulière des Anomalies de l'Organisation chez l'Homme et les Animaux, ou Traité de Tératologie*, the third and concluding volume of which did not appear till 1837. This work is of extreme value, and will always serve as the starting-point for those who may occupy themselves with this important branch of biological investigation. Having for a long time the superintendence of the menagerie of the museum, he was led to study the domestication of foreign animals in France; and the results of these investigations may be found in his *Domestication et Naturalisation des Animaux Utiles* (1854), and especially in the *Société pour l'Acclimatation des Animaux Utiles*, of which he was the founder. In 1852, he published the first volume of a great work entitled, *Histoire Générale des Règnes Organiques*, in which he intended to develop the doctrines handed down to him by his father, but which is left in an unfinished state by his premature death. He was a strong advocate of the use of horse-flesh as human food, and published his *Lettres sur les Substances Alimentaires, et particulièrement sur la*

Viande de Cheval (1856), with the view of bringing his views on the subject before the general public.

GEOGNOSY (gē, the earth; gnōsis, knowledge) is a term now little used by British writers, but still employed in Germany as a synonym of geology, or, more properly, as restricted to the observed facts of geology, apart from reasonings or theories built upon them. The geognost examines the nature and position of the rocks of a country, without grouping them together in the order of succession. Of necessity, geognosy preceded geology; it was indeed geology in its early empirical condition, when it consisted merely of a record of observed facts; but as soon as these assumed a scientific form, and were arranged into a system, then geognosy disappeared; for even in the examination of new and unexplored territories, the data supplied by the science of geology enable us to refer the strata with certainty to their true chronological position.

The word has also been employed to designate that department of geology which treats of the physical characteristics of rocks; that is, of their chemical composition, internal structure, planes of division, position and other properties, and peculiarities belonging to them simply as rocks.

GEOGRAPHICAL DISTRIBUTION OF ANIMALS. Each great geographical or climatal region of the globe is occupied by some species of animals not found elsewhere. Thus, the ornithorhynchus belongs exclusively to New Holland; the sloth, to America; the hippopotamus and camelopard, to Africa; and the reindeer and walrus, to the arctic regions; and each of these animals, when left in its natural freedom, dwells within certain limits, to which it always tends to return, if removed by accident or design. A group of animals inhabiting any particular region, and embracing all its species, both aquatic and terrestrial, is called its FAUNA (q. v.), just as the collective plants of a country are termed its FLORA. There is a close and obvious connection between the fauna of any place and its temperature, although countries with similar climates are not always inhabited by similar animals; and the soil and vegetation are likewise important factors in determining the characters of any special fauna.

The influence of climate is well seen in the distribution of animals in the arctic regions. The same animals inhabit the northern polar regions of Europe, Asia, and America. Thus, for example, the polar bear, whales, seals, and numerous birds, are common to the northern regions of these three continents. In the temperate regions, on the other hand, the types remain the same, but they are represented by different species, which still, however, retain the same general features. These general resemblances often led our early American colonists erroneously to apply the names of European species to the similar, but not identical animals of the New World. Similar differences occur in distant regions of the same continent, within the same parallel of latitude. Thus, as Professor Agassiz has remarked, the animals of Oregon and of California are not the same as those of New England; and the difference, in some respects, is even greater than between the animals of New England and Europe; and similarly, the animals of temperate Asia differ more from those of Europe, with which they are continuous, than they do from those of America, from which they are separated by a large surface of ocean.

Under the torrid zone, we not only find animals different from those occurring in temperate regions, but we likewise meet with a fauna which presents the greatest variety amongst the individuals which constitute it. 'The most gracefully proportioned

GEOGRAPHICAL DISTRIBUTION OF ANIMALS.

forms,' says Agassiz, 'are found by the side of the most grotesque, decked with every combination of brilliant colouring. At the same time, the contrast between the animals of different continents is more marked; and in many respects, the animals of the different tropical faunas differ not less from each other than from those of the temperate or frozen zones; thus, the fauna of Brazil varies as much from that of Central Africa as from that of the Southern United States. This diversity in different continents cannot depend simply upon any influence of the climate of the tropics; if it were so, uniformity ought to be restored in proportion as we recede from the tropics towards the antarctic temperate region. But instead of this, the differences continue to increase—so much so, that no faunas are more in contrast than those of Cape Horn, the Cape of Good Hope, and New Holland. Hence, other influences must be in operation besides those of climate, &c.—influences of a higher order, which are involved in a general plan, and intimately associated with the development of life on the surface of the earth.' If space permitted, we might point out the influence of the natural features of the earth's surface in limiting and separating faunas. A mountain chain or a desert may act as effectually as the depths of ocean in separating one fauna from another. When no such obstacles exist, one fauna gradually merges into another, without any definite line of demarcation.

The powers of locomotion possessed by different animals have not—as we might have supposed—any apparent influence on the extent of country over which they range. On the contrary, animals whose locomotive powers are extremely small, as, for example, the common oyster, have a far greater range than some of our fleet animals, such as the moose.

'The nature of their food has an important bearing upon the grouping of animals, and upon the extent of their distribution. Carnivorous animals are generally less confined in their range than herbivorous ones, because their food is almost everywhere to be found. The herbivora, on the other hand, are restricted to the more limited regions corresponding to the different zones of vegetation.' Similarly, birds of prey, like the eagle and vulture, have a much wider range than the granivorous and gallinaceous birds; but even the birds that wander furthest, have their definite limits; for example, the condor of the Cordilleras, although, from the extreme heights at which he is often seen, he cannot fear a low temperature, is never found in the temperate region of the United States.

A very influential factor is the distribution of aquatic animals in the depths of water. The late Professor Forbes distinctly shewed that we may recognise distinct faunas in zones of different depth, just as we mark different zones of animal and vegetable life in ascending lofty mountains. The zoophytes, molluscs, and even fishes, found near the shore in shallow water, usually differ very materially from those living at the depth of 20 or 30 feet; and these, again, are different from those which are met with at a greater depth. The extreme depth at which animal life, in its lower forms, ceases to exist, is unknown; late researches of Dr Wallich and Alphonse Milne Edwards shew, however, from the evidence of deep-sea soundings, and of pieces of telegraph wire raised from great depths, that the region of animal life extends *bathymetrically* (to use Professor Forbes's word) further than was anticipated.

Before concluding these general remarks, we must observe that occasionally one or more animals are found in one very limited spot, and nowhere else; as,

for example, the chamois and the ibex upon the Alps. (On this point, the reader should consult Darwin's *Journal of Researches*, &c., in which it is shewn that the Galapagos Archipelago, consisting of a small group of islands situated under the equator, and between 500 and 600 miles westward of the coast of America, not only contain numerous animals and plants that are found in no other part of the world, but that many of the species are exclusively confined to a single island.)

All the faunas of the globe may be divided into three great groups, corresponding to the three great climatal divisions—viz., the Arctic or Glacial, the Temperate, and the Tropical Faunas, while the two last-named faunas may be again divided into several zoological provinces. Each of these primary divisions demands a separate notice.

ARCTIC FAUNA.—The limits of this fauna are easily fixed, as we include within them all animals living beyond the line where forests cease, and are succeeded by vast arid plains, known as barren lands, or *tundras*. Though the air-breathing species are not numerous here, the large number of individuals compensates for this deficiency, and among the marine animals we find an astonishing profusion and variety of forms. The larger mammals which inhabit this zone are the white bear, the walrus, numerous species of seal, the reindeer, the musk-ox, the narwal, the cachalot, and whales in abundance. Among the smaller species, we may mention the white fox, the polar hare, and the lemming. Some marine eagles and a few wading birds are found; but the aquatic birds of the family of *Palmipedes* (the web-footed birds), such as the gannets, cormorants, penguins, petrels, ducks, geese, mergansers, and gulls, abound in almost incredible profusion. No reptile is known in this zone. Fishes are very numerous, and the rivers especially swarm with a variety of species of the salmon family. The *Articulata* are represented by numerous marine worms, and by minute crustaceans of the orders *Isopoda* and *Amphipoda*; insects are rare, and of inferior types (only six species of insects were observed in Melville Island during Parry's residence of eleven months there). Only the lowest forms of molluscs are found, viz., *Tunicata* and *Acephala*, with a few *Gasteropoda*, and still fewer *Cephalopoda*. The *Radiata* are represented by numerous jelly-fishes (especially the *berœe*), by several star-fishes and echini, and by very few polypes.

With this fauna is associated a peculiar race of men, known in America under the name of Esquimaux (q. v.), and in the Old World under the names of Laps, Samoyedes, and Tchuktsches. 'This race,' says Agassiz, 'differs alike from the Indians of North America, from the whites of Europe, and the Mongols of Asia, to whom they are adjacent. The uniformity of their characters along the whole range of the arctic seas, forms one of the most striking resemblances which these people exhibit to the fauna with which they are so closely connected.'

TEMPERATE FAUNAS.—To the glacial zone, which encloses a single fauna, succeeds the temperate zone, included between the isothermes (or lines of equal mean temperature) of 32° and 74°, characterised by its pine-forests, its maples, its walnuts, and its fruit-trees, and inhabited by the terrestrial bear, the wolf, the fox, the weasel, the marten, the otter, the lynx, the horse and ass, the boar, numerous genera and species of deer, goats, sheep, oxen, hares, squirrels, rats, &c.; and southwards by a few representatives of the tropical zone. Considering the whole range of the temperate zone from east to west, Agassiz divides it, in accordance with the prevailing physical features, into—1st, the *Asiatic* realm, embracing Manchuria, Japan, China,

GEOGRAPHICAL DISTRIBUTION OF ANIMALS.

Mongolia, and passing through Turkestan into, 2d, the *European* realm, which includes Iran, Asia Minor, Mesopotamia, Northern Arabia and Barbary, as well as Europe properly so called; the western parts of Asia and the northern parts of Africa being intimately connected by their geological structure with the southern part of Europe; and 3d, the *North American* realm, which extends as far south as the table-land of Mexico.

The temperate zone is not characterised, like the arctic, by one and the same fauna. Not only are the animals different in the eastern and western hemispheres, but there are differences in the various regions of the same hemisphere: as we before remarked, the species resemble, but are not identical with one another. Thus, in Europe, we have the brown bear; in North America, the black bear; and in Asia, the bear of Tibet; the common stag or red deer of Europe is represented in North America by the Canadian stag or wapiti and the American deer, and in Eastern Asia by the musk-deer; the North American buffalo is represented in Europe by the wild aurochs of Lithuania, and in Mongolia by the yak; and numerous other examples might readily be given.

The marked changes of temperature between the different seasons occasion migrations of animals more in this zone than any other, and this point must not be overlooked by the naturalist in determining the fauna of a locality within it. Many of the birds of Northern Europe and America, in their instinctive search for a warmer winter climate, proceed as far southward as the shores of the Mediterranean and of the Gulf of Mexico. See **MIGRATIONS OF ANIMALS.**

Amongst the most characteristic of the animals of the *Asiatic* realm, we may mention the bear of Tibet, the musk-deer, the tzeiran (*Antelope gutturosa*), the Mongolian goat, the argali, the yak, the Bactrian or double-humped camel, the wild horse, the wild ass, and another equine species, the dtschigetai (*Equus hemionus*). The nations of men inhabiting these realms all belong to the so-called Mongolian race.

That the *European* is a distinct zoological realm, seems to be established, says Agassiz, 'by the range of its mammalia, and by the limits of the migrations of its birds, as well as by the physical features of its whole extent. Thus we find its deer or stag, its bear, its hare, its squirrel, its wolf and wild cat, its fox and jackal, its otter, its weasel and marten, its badger, its bear, its mole, its hedgehogs, its bats, &c. Like the eastern realm, the European world may be subdivided into a number of distinct faunas, characterised each by a variety of peculiar animals. In Western Asia, we find, for instance, the common camel instead of the Bactrian; whilst Mount Sinai, Mounts Taurus and Caucasus, have goats and wild sheep which differ as much from those of Asia as from those of Greece, the Alps, the Atlas, or of Egypt.' There is no reason for our referring, as many writers have done, our chief domesticated animals to an Asiatic origin. A wild horse, different in species from the Asiatic breeds, once inhabited Spain and Germany, and a wild bull existed over the whole range of Central Europe. The domesticated cat, whether we trace it to *Felis maniculata* of Egypt or to *Felis catus* (the wild cat) of Central Europe, belongs to this realm; and whatever theory be adopted regarding the origin of the dog, the European realm forms its natural range. The merino sheep is still represented in the wild state by the mouflon of Sardinia, and formerly ranged over all the mountains in Spain. The hog is descended from the common boar, still found wild over most of the temperate zone of the Old World. Ducks, geese, and pigeons have their wild representatives in

Europe. The common fowl and the turkey are, on the other hand, not indigenous, the former being of East Asiatic, and the latter of American origin. The reader will observe that the European zoological realm is circumscribed within exactly the same limits as the so-called white race of man.

The *American* realm contains many animals not found in Europe or Asia, amongst which we may mention the opossum; several species of insectivora, as, for example, the shrew-mole (*Scalops aquaticus*) and the star-nosed mole (*Condylura cristata*), several species of rodents (especially the musk-rat), the Canadian elk, &c., in the northern portion; and the prairie-wolf, the fox-squirrel, &c., in the southern portion of the fauna. Amongst other types characteristic of this zone must be reckoned the snapping-turtle among the tortoises; the *Menobanchus* and *Menopoma* among the salamanders; and the rattlesnake among the serpents; and the *Lepidosteus* and the *Amia*, important representatives of two almost extinct families, among the fishes.

The faunas of the southern temperate region differ from one another more than those of the corresponding northern region. 'Each of the three continental peninsulas jutting out southerly into the ocean represents, in some sense, a separate world. The animals of South America beyond the tropic of Capricorn are in all respects different from those at the southern extremity of Africa. The hyenas, wild boars, and rhinoceroses of the Cape of Good Hope have no analogies on the American continent; and the difference is equally great between the birds, reptiles, fishes, insects, and mollusca. New Holland, with its marsupial mammals, with which are associated insects and molluscs no less singular, furnishes a fauna still more peculiar, and which has no similarity to those of any of the adjacent countries. In the seas of that continent, we find the curious shark, with paved teeth and spines on the back (*Cestracion Philippii*), the only living representative of a family so numerous in former zoological ages.'

TROPICAL FAUNAS are distinguished in all the continents by the immense variety of animals which they contain, and in many cases by the brilliancy of their colour. Not only are all the principal types of animals represented, but genera, species, and individuals occur in abundant profusion. The tropical is the region of the apes and monkeys (which seem to be naturally associated with the distribution of the palms, which furnish to a great extent the food of the monkeys on both continents), of herbivorous bats, of the great pachyderms, such as the elephant, the hippopotamus, and the tapir, and of the whole family of edentata. Here, too, are the largest of the cats, the lion and the tiger. Among birds, the parrots and toucans are essentially tropical; amongst the reptiles, the largest serpents, crocodiles, and tortoises belong to this zone, as also do the most gorgeous insects. The marine fauna is also superior in beauty, size, and number to those of other regions. The tropical fauna of each continent furnishes new and peculiar forms. Sometimes whole types are restricted to one continent, as the sloths, the toucans, and the humming-birds to America; the gibbons, the red orang, the royal tiger, and numerous peculiar birds to Asia; and the giraffe and hippopotamus to Africa: while sometimes animals of the same group present different characteristics on different continents. Thus, for example, the American monkeys have flat and widely separated nostrils, thirty-six teeth, and generally a long prehensile tail; while the monkeys of the Old World have their nostrils close together, only thirty-two teeth, and non-prehensile tails.

GEOGRAPHICAL DISTRIBUTION OF PLANTS.

The island of Madagascar has its peculiar fauna. A large number of species of quadrupeds, cheiroptera, insectivora, &c., are found only in this island; and of 112 species of birds that have been described, 65, or more than half, are found nowhere else. We have already referred to the still more exclusive fauna of the Galapagos Islands, which has been specially studied by Darwin.

From a general survey of such facts as we have given in a very condensed form in the preceding columns, Agassiz draws the following conclusions:

1. Each grand division of the globe has animals which are either wholly or for the most part peculiar to it.

2. The diversity of faunas is not in proportion to the distance that separates them. Very similar faunas are found at great distances apart, while very different faunas are found at comparatively short distances.

3. There is a direct relation between the richness of a fauna and the climate, and likewise between the fauna and the flora; the limit of the former being oftentimes determined, so far as terrestrial animals are concerned, by the extent of the latter.

4. The distribution of animals cannot (any more than their organisation) be the effect of external influences, but is the realisation of a wisely designed plan, by which each species of animal was originally created at the place and for the place which it inhabits. The only way to account philosophically for the distribution of animals as we now find them, is to regard them as *autochthonoi*—that is to say, as originating on the soil where they exist. There is not a single fact in favour of, indeed, all scientific observations are in direct opposition to the view, that the whole animal world was created in one single centre.

For further details on this subject, we may refer to the various works of Agassiz, of which we have made free use in the compilation of this article; to Vogt's *Zoologische Briefe*, vol. ii.; Mrs Somerville's *Physical Geography*, vol. ii.; Maury's *La Terre et l'Homme*; Klöden's *Handbuch der Physischen Geographie*; and especially to Schmarda's great work on the subject, entitled *Die Geographische Verbreitung der Thiere*.

GEOGRAPHICAL DISTRIBUTION OF PLANTS, also called **GEOGRAPHICAL BOTANY**, and **PHYTOGEOGRAPHY**, is that branch of botany which treats of the geographic distribution of plants, and connects botany with physical geography. A knowledge of facts belonging to it has been gradually accumulating ever since the science of botany began to be studied, but its importance was little understood until very recent times. Humboldt may be said to have elevated it to the rank which it now holds as a distinct branch of science. It was indeed impossible for botany to be studied without attention being arrested by the great diversity of the productions of different countries, and even of those not very dissimilar in climate. But it was long ere important generalisations were attempted; and a large accumulation of particular facts was in the first place necessary. Even to this day, the deficiency of information concerning the botany of wide regions is painfully felt.

Every climate has plants particularly adapted to it. The plants of the tropics will not grow in frigid, nor generally even in temperate regions; as little will arctic or subarctic plants endure the heat of the torrid zone. And as the climate changes with the elevation above the level of the sea, the mountains of tropical countries have a flora analogous to that of the temperate, and even of the frigid zones. The vegetation of every place bears a relation to its mean annual temperature. But owing to the

peculiarities of different plants, it bears also important relations to the mean temperatures of the summer and winter months; and thus great diversities are found not only in the indigenous vegetation of countries very similar in their mean annual temperature, but even in their suitability for plants which may be introduced into them by man. Nor is temperature the only thing of importance in the relations of climate to vegetation. Moisture must be ranked next to it. Some plants flourish only in a dry, and some only in a humid atmosphere. The flora of the very dry regions of Africa and of Australia is almost as notably different from that of moist countries in similar latitudes, as that of the temperate from that of the torrid zone. Nor is the difference merely in the species of plants produced, but in the whole character of the vegetation, which very much consists either of succulent plants with thick epidermis, or of plants with hard and dry foliage.

Much depends also on soil. Sandy soils have their peculiar vegetation; peat is also favourable to the growth of many plants which are seldom or never to be found in any other soil. The chemical constitution of soils determines to some extent the character of their flora; and therefore certain plants are almost exclusively to be found in districts where certain rocks prevail, and a relation is established between botany and geology. Limestone districts, for example, have a flora differing to a certain extent from other districts even of the same vicinity. Some British plants are almost entirely limited to the chalk districts. The other physical qualities of the soil are not unimportant. Light soils are suitable to plants with fine roots divided into many delicate fibrils, as heaths, which will scarcely grow in stiff clay.

Some groups of plants are almost entirely limited to peculiar situations, as the *Algae* and other smaller groups of *aquatic* plants. Some are exclusively tropical; others are only found in the colder parts of the world; and if any of the group occur within the tropics, it is on mountains of considerable elevation. But besides all this, and apart from all obvious differences of climate, soil, &c., some groups of plants, and these often containing many species, are only or chiefly found in certain parts of the world. Thus the *Cactaceae* are exclusively American; whilst of the numerous species of Heath (*Erica*), not one is indigenous to America, although many other plants of the Heath family (*Ericaceae*) are so. Sometimes the plants which chiefly abound in one part of the world seem to be replaced by other but similar species, sometimes by those of another group, in another part of the world, with similar physical characteristics. Thus *Mesembryaceae* and *Crassulaceae* seem in some countries to occupy the place of the American *Cactaceae*, whilst the black-fruited Crowberry (*Empetrum*) of the northern parts of the world finds a representative in a red-fruited species, extremely similar, in the southern parts of South America. Of many groups which chiefly belong to certain climates or certain parts of the world, there are yet species which wander, as it were, into very different climates or remote parts of the world; these species being often, however, unknown where the other species of the group abound. Thus the common periwinkle is a northern wanderer of a family mostly tropical. Some groups are common to parts of the world widely remote, and their prevalence is characteristic of these parts, as *Rhododendrons* and *Magnoliaceae* of North America and of the mountainous districts of the East Indies, although the American and the Asiatic species are not the same. Some species are believed to exist only within a very narrow range; others are very widely

diffused. A few are found in the colder parts both of the northern and southern hemispheres, and also on the intervening tropical mountains. Some groups also, containing many species, are confined to particular regions, as the important *Cinchona* to a district of the Andes, and the *Calceolaria* to higher parts of the same mountain chain.—Marine vegetation, like terrestrial vegetation, has species and groups that are very generally diffused, and others confined to particular regions.

The geographical limits of species have no doubt been in many instances unintentionally modified by man, and the extent of this modification it is extremely difficult to ascertain. There is enough, however, in the known facts of botanical geography, evidently independent of such agency, to afford foundation for interesting and important speculations, of which some notice will be taken under the head SPECIES.

Many of the principal facts of botanical geography will be found stated in the articles EUROPE, ASIA, AMERICA, and AUSTRALIA, and in articles on natural orders and genera of plants. Schouw and Meyen are among the chief authorities on this subject; and the former has endeavoured to divide the earth into 25 botanical regions, characterised by the prevalence of particular forms of vegetation. The reader will find much information on botanical geography, collected in a very accessible form, in the *Physical Atlas* of Johnston and Berghaus.—Hendrey's *Vegetation of Europe* (Van Voorst, London, 1852) may be consulted with advantage; and the *Cybele Britannica*, and *Geography of British Plants*, of Mr H. C. Watson, treating of the geographic distribution of plants in the British Isles, are unrivalled among works of this kind.

GEOGRAPHY (Gr. *gē*, the earth, *graphō*, to write or describe) is, as its name implies, a description of the earth. This science is best considered under the three distinct heads of *Mathematical* or *Astronomical* Geography, *Physical* Geography, and *Political* Geography, which all admit of further subdivision into numerous subsidiary branches.

Mathematical or *Astronomical* Geography describes the earth in its planetary relations as a member of the solar system, influencing and influenced by other cosmical bodies. It treats of the figure, magnitude, and density of the earth; its motion, and the laws by which that motion is governed; together with the phenomena of the movements of other cosmical bodies, on which depend the alternation of day and night, and of the seasons of the year, and the eclipses and occultations of the sun, moon, and planets; it determines position, and estimates distances on the earth's surface, and teaches methods for the solution of astronomical problems, and the construction of the instruments necessary for such operations, together with the modes of representing the surface of the earth by means of globes, charts, and maps. The numerous subjects comprised in this portion of geographical science will be found in other parts of the present work, and we therefore refer our readers for further particulars to the several articles in which they are more fully treated, as, for instance, ASTRONOMY, LATITUDE AND LONGITUDE, MATHEMATICAL INSTRUMENTS, OBSERVATORIES, &c.

Physical Geography, as the name indicates, considers the earth in its relation to nature and natural or physical laws only. It describes the earth, air, and water, and the organised beings, whether animal or vegetable, by which those elements are occupied, and considers the history, extent, mode, and causes of the distribution of these beings. This may be regarded as the most important branch of geographical science, since it involves the consideration and study of phenomena, which not only tend to further

the material interests of man, by teaching him how best to promote the development of the products of nature, but also conduce in no inconsiderable degree to general intellectual advance, by stimulating the faculties of observation, and exercising the powers of thought. The vast sphere of inquiry included in physical geography necessarily embraces the consideration of all the natural sciences generally, and we can here, therefore, merely refer our readers for more special information regarding the details of the subject to such articles as CLIMATE, HEAT, LAKES, RIVERS, MOUNTAINS, OCEAN, WINDS, RAIN, CLOUDS; ETHNOLOGY, GEOGRAPHICAL DISTRIBUTION OF ANIMALS AND PLANTS, &c.

Political Geography has been well defined as 'including all those facts which are the immediate consequences of the operations of man, exercised either on the raw materials of the earth, or on the means of his intercourse with his fellow-creatures.' Thus considered, it embraces, primarily, the description of the political or arbitrary divisions and limits of empires, kingdoms, and states; and, secondarily, that of the laws, modes of government, and social organisation which prevail in the several countries. The details of this branch of geography will be found under the names of countries, cities, &c., while more general information in regard to the subject must be sought from historical, political, and statistical sources.

Before proceeding to sketch the progress and history of geographical discovery, we will indicate a few of the leading works that afford the best aid in studying the three main branches of geography to which we have referred. Thus, for instance, in *Mathematical* Geography, we would specially instance: *Manual of Geographical Science* (Part I. *Mathematical Geography*, by Mr O'Brien); Herschel's *Outlines of Astronomy*; Klöden's *Erdkunde* (Part I.); in *Physical* Geography, Ritter's *Erdkunde*; Klöden's; A. Maury's *La Terre et l'Homme*; Mrs Somerville's *Physical Geography*; Mr F. Maury's *Physical Geography of the Sea*, &c.: while in regard to *Political* Geography, information may be sought from the great works of Ritter, Berghaus, Stein, Wappäus, and Klöden, and from the ordinary geographical manuals and maps.

Geographical Discovery.—The earliest idea formed of the earth by nations in a primeval condition seems to have been that it was a flat circular disc, surrounded on all sides by water, and covered by the heavens as with a canopy, in the centre of which their own land was supposed to be situated. The Phœnicians were the first people who communicated to other nations a knowledge of distant lands; and although little is known as to the exact period and extent of their various discoveries, they had, before the age of Homer, navigated all parts of the Euxine, and penetrated beyond the limits of the Mediterranean into the Western Ocean, and they thus form the first link of the great chain of discovery which, 2500 years after their foundation of the cities of Tartessus and Utica, was carried by Columbus to the remote shores of America. Besides various settlements nearer home, these bold adventurers had founded colonies in Asia Minor about 1200 B.C., and a century later they laid the foundation of Gades, Utica, and several other cities, which was followed, in the course of the 9th c. by that of Carthage, from whence new streams of colonisation continued for several centuries to flow to hitherto unknown parts of the world. The Phœnicians, although less highly gifted than the Egyptians, rank next to them in regard to the influence which they exerted on the progress of human thought and civilisation, for their knowledge of mechanics, their early use of weights and measures,

GEOGRAPHY.

and what was of still greater importance, their employment of an alphabetical form of writing, facilitated and confirmed commercial intercourse among their own numerous colonies, and formed a bond of union which speedily embraced all the civilised nations of Semitic and Hellenic origin. So rapid was the advance of geographical knowledge between the age of the Homeric poems (which may be regarded as representing the ideas entertained at the commencement of the 9th c. B.C.) and the time of Hesiod (800 B.C.), that while in the former the earth is supposed to resemble a circular shield, surrounded by a rim of water, spoken of as the parent of all other streams, and the names of Asia and Europe applied only, the former to the upper valley of the Caister, and the latter to Greece north of Peloponnesus, Hesiod mentions parts of Italy, Sicily, Gaul, and Spain, and is acquainted with the Scythians, and with the Ethiopians of Southern Africa. During the 7th c. B.C., certain Phœnicians, under the patronage of Neku or Necho II. king of Egypt, undertook a voyage of discovery, and are supposed to have circumnavigated Africa. This expedition is recorded by Herodotus, who relates that it entered the Southern Ocean by way of the Red Sea, and after three years' absence, returned to Egypt by the Pillars of Hercules. The fact of an actual circumnavigation of the African continent has been doubted, but the most convincing proof of its reality is afforded by the observation which seemed incredible to Herodotus, viz., 'that the mariners who sailed round Libya (from east to west) had the sun on their right hand.' The 7th and 6th centuries B.C. were memorable for the great advance made in regard to the knowledge of the form and extent of the earth. Thales, and his pupil Anaximander, reputed to have been the first to draw maps, exploded many errors, and paved the way, by their observations, for the attainment of a sounder knowledge. The logographers contributed at this period to the same end by the descriptions which they gave of various parts of the earth; of these, perhaps the most interesting to us is the narrative of the Carthaginian Himilco, who discovered the British Islands, including the *Cestrýmnides*, which he described as being a four months' voyage from Tartessus.

With Herodotus of Halicarnassus (born 484 B.C.), who may be regarded as the father of geography as well as of history, a new era began in regard to geographical knowledge, for although his chief object was to record the struggles of the Greeks and Persians, he has so minutely described the countries which he visited in his extensive travels (which covered an area of more than 31° or 1700 miles from east to west, and 24° or 1660 miles from north to south), that his History gives us a complete representation of all that was known of the earth's surface in his age. This knowledge, which was extremely scanty, consisted in believing that the world was bounded to the south by the Red Sea or Indian Ocean, and to the west by the Atlantic, while its eastern boundaries, although admitted to be undefined, were conjectured to be nearly identical with the limits of the Persian empire, and its northern termination somewhere in the region of the amberlands of the Baltic, which had been visited by Phœnician mariners, and with which the people of Massilia (the modern Marseille) kept up constant intercourse by way of Gaul and Germany. In the next century, the achievements of Alexander the Great tended materially to enlarge the bounds of human knowledge, for while he carried his arms to the banks of the Indus and Oxus, and extended his conquests to Northern and Eastern Asia, he at the same time promoted science, by sending expeditions

to explore and survey the various provinces which he subdued, and to make collections of all that was curious in regard to the organic and inorganic products of the newly visited districts; and hence the victories of the Macedonian conqueror formed a new era in physical inquiry generally, as well as in geographical discovery specially. While Alexander was opening the East to the knowledge of western nations, Pytheas, an adventurous navigator of Massilia, conducted an expedition past Spain and Gaul through the Channel, round the east of England into the Northern Ocean, where, after six days' sailing, he reached Thule (conjectured to be Iceland), and returning, passed into the Baltic, where he heard of the Teutones and Goths. Discovery was thus being extended both in the north and east into regions whose very existence had never been suspected, or which had hitherto been regarded as mere chaotic wastes. An important advance in geography was made by Eratosthenes (born 276 B.C.), who first used parallels of longitude and latitude, and constructed maps on mathematical principles. Although his work on geography is lost, we learn from Strabo that he considered the world to be a sphere revolving with its surrounding atmosphere on one and the same axis, and having one centre. He believed that only about one-eighth of the earth's surface was inhabited, while the extreme points of his habitable world were Thule in the north, China in the east, the Cinnamon Coast of Africa in the south, and the Prom. Sacrum (Cape St Vincent) in the west. During the interval between the ages of Eratosthenes and Strabo (born 66 B.C.), many voluminous works on geography were compiled, which have been either wholly lost to us, or only very partially preserved in the records of later writers. Strabo's great work on geography, which is said to have been composed when he was eighty years of age, has been considered as a model of what such works should be in regard to the methods of treating the subject; but while his descriptions of all the places he has himself visited are interesting and instructive, he seems unduly to have discarded the authority of preceding writers.

The wars and conquests of the Romans had a most important bearing upon geography, since the practical genius of the Roman people led them to the study of the material resources of every province and state brought under their sway, and the greatest service was done to geographical knowledge by the survey of the empire, which was begun by Julius Cæsar, and completed by Augustus. This work comprised a description and measurement of every province by the most celebrated geometers of the day. Pliny (born 23 A.D.), who had travelled in Spain, Gaul, Germany, and Africa, has left us a compendium of the geographical and physical science of his age in the four books of his *Historia Naturalis* which he devotes to the subject. He collected with indefatigable industry the information contained in the works of Sallust, Cæsar, Tacitus, and others, to which he added the results of his own observations, without, however, discriminating between fact and fiction. The progress that had been made since Cæsar's time in geographical knowledge is evinced by Pliny's notice of arctic regions and of the Scandinavian lands, and the accounts which he gives of Mount Atlas, the course of the Niger, and of various settlements in different parts of Africa; while his knowledge of Asia is more correct than that of his predecessors, for he correctly affirms that Ceylon is an island, and not the commencement of a new continent, as had been generally supposed. The study of geography in ancient times may be said to have terminated with C. Ptolemy, who flourished in the middle of the 2d c. of our era. His work

on Geography, in eight books, which continued to be regarded as the most perfect system of the science through the dark and middle ages down to the 16th c., gives a tolerably correct account of the well-known countries of the world, and of the Mediterranean, Euxine, and Caspian, together with the rivers which fall into those seas, but it added little to the knowledge of the north of Europe, or the extreme boundaries of Asia or Africa. Yet, from his time till the 14th c., when the records of the travels of the Venetian Marco Polo opened new fields of inquiry, the statements of Ptolemy were never questioned, and even during the 15th c., it was only among a few German scholars at Nürnberg that the strange accounts given of distant eastern lands by the Venetian traveller were received as trustworthy where he differed from Ptolemy. Marco Polo had, however, unfortunately made no astronomical observations, nor had he even recorded the length of the day at any place, and hence the Nürnberg geographers, who had no certain data for estimating the extent of the countries which he had traversed, were the means of propagating errors which led to results that were destined to influence the history of mankind; for taking Ptolemy's tables as their basis, they had incorporated on their globes and maps the results of their own rough estimates of the length of Marco Polo's days' journeys, and they had thus represented the continent of Asia as extending across the Pacific, and having its eastern shores somewhere in the region of the Antilles. These erroneous calculations misled Christopher Columbus to the false assumption that, by sailing 120° west, he would reach the wealthy trading marts of China, and the result of this conviction was his entering upon that memorable expedition which terminated in the discovery (in 1492) of the continent of America. Although there can be no doubt that the American continent was visited in the 9th and 10th c. by Northmen, the event remained without influence on the history of discovery, and cannot therefore detract from the claims of Columbus. This momentous discovery, which had been preceded in 1486 by the exploration of the African coast as far as the Cape of Good Hope (which was doubled by Vasco da Gama in 1497), was followed by a rapid succession of discoveries; and within 30 years of the date of the first voyage of Columbus, the whole coast of America from Greenland to Cape Horn had been explored, the Pacific Ocean had been navigated, and the world circumnavigated by Magellan (q. v.); the coasts of Eastern Africa, Arabia, Persia, and India had been visited by the Portuguese, and numerous islands in the Indian Ocean discovered. The 16th c. was marked by continued attempts, successful and unsuccessful, to extend the sphere of oceanic discovery; and the desire to reach India by a shorter route than those by the Cape of Good Hope or Cape Horn, led to many attempts to discover a north-west passage, which, though they signally failed in their object, had the effect of very materially enlarging our knowledge of the arctic regions. The expeditions of Willoughby and Frobisher, in 1553 and 1576, of Davis (1585), Hudson (1607), and Baffin (1616), were the most important in their results towards this end. The 17th and 18th centuries gave a new turn to the study of geography, by bringing other sciences to bear upon it, which, in their turn, derived elucidation from the extension of geographical knowledge; and it is to the aid derived from history, astronomy, and the physical and natural sciences, that we owe the completeness which has characterised modern works on geography. In the 17th c., the Dutch, under Tasman and Van Diemen, made the Australasian

islands known to the civilised world; and in the latter half of the 18th c., Captain Cook extended the great oceanic explorations by the discovery of New Zealand and many of the Polynesian groups; but he failed to find the antarctic continent, which was first visited in 1840 by American, English, and French expeditions, under their respective commanders, Wilkes, Ross, and Dumont d'Urville. This will probably prove to have been among the last of great oceanic discoveries; and the attention of explorers is now turned to the interior of the great continents. In America, the travels of Humboldt, Lewis and Clark, Fremont, and others, have done much to make us acquainted with broad general features, but much remains to be done in regard to special districts of Central and Southern America. In Asia, numerous travellers, geographers, and naturalists have contributed to render our knowledge precise and certain in respect to a great part of the continent, whose natural characteristics have been more especially represented by the great physicist Ritter; while we owe a large debt of gratitude to the Jesuit missionaries, whose indefatigable zeal has furnished us with a rich mass of information in regard to minor details of Asiatic life and nature. In Africa, the combined influences of a deleterious climate, and a religion hostile to European advance, have hitherto retarded explorations into the interior; but notwithstanding these obstacles, much light has been thrown on the character and condition of the African continent by many of its greatest explorers—as Bruce, Park, Clapperton, Adanson, the Landers, Burton, Speke, Barth, Vogel, and Livingstone. In Australia, although much still remains to be done, the obscurity which had hitherto hung over the interior has been to a great extent diminished by the explorations of Sturt, Eyre, Leichhardt, and the brothers Gregory; and still more by the highly important labours of Burke and Wills, who in 1860 crossed the Australian continent from Melbourne to Carpentaria. Although both these intrepid explorers perished miserably from starvation on their return route, their journals and the description that has been given by them and their sole-surviving companion, King, of the country through which they passed, prove that the land is far from being the desert it was once imagined to be.

The progress which has marked recent discovery has been materially aided by the encouragement and systematic organisation which have been given to plans of exploration by the public governments of different countries, and by the efforts of the numerous geographical societies which have been formed during the present century both at home and abroad; while the constantly increasing mass of information collected by scientific explorers is rapidly diffusing correct information in regard to distant regions, and thus effectually dispelling the numerous fallacies which have hitherto obscured the science of geography. Among the numerous works of authority on the subject of geographical discovery, the following may be consulted with advantage: Hudson's *Geographi Græci minores*; *Précis de Géographie Universelle*, by Malte Brun; *Manual of Geographical Science* (mathematical, physical, historical, and descriptive), 1860; Latham's *Germania of Tacitus*; Humboldt's *Hist. crit. de l'Hist. de la Géographie, Asie Centrale, and the Cosmos*, Ritter's *Asien*; and *Die Erdkunde im Verhältnisse z. Natur u. d. Gesch. d. Menschheit*; Petermann, *Mittheilungen aus J. Perthes' Geographischer Anstalt* (1855—1857); *Proceedings of Geographical Society*, &c.

GEOGRAPHY, MEDICAL. The liability of particular localities to become the centres of special diseases, or groups of diseases, has been observed

from the most ancient periods, as we have excellent evidence in the Hippocratic treatise, *On Airs, Waters, and Places*, one of the undoubtedly genuine works of the great Greek physician, and one of those which best sustains his traditional reputation. Now-a-days, medical geography has become a most elaborate and carefully investigated branch of medical science, the details of which, though of considerable popular interest, are far too complicated and too technical to be discussed with advantage here. The reader may be referred to the articles ENDEMIC DISEASE, CLIMATE, AGUE, DYSENTERY, GOITRE, LEPROSY, YELLOW FEVER, PLAGUE, REMITTENT FEVER, for incidental illustrations of the subject. Generally speaking, the tropics are subject to diarrhoeal diseases, with acute affections of the liver, and severe remittent or pestilential fevers, caused by the exalted temperature acting on the soil, and producing emanations very destructive of health; the like causes in more temperate climates causing ague and diarrhoea, especially during the summer and autumn, in low-lying, ill-drained localities. Temperate climates are also subject to a peculiar degree to pulmonary diseases, and to all manner of contagious fevers, the result of overcrowding and confined air. Certain diseases, again, as goitre, leprosy, and some animal parasites (see ENTOMOLOGY), appear to have no relation to climate, but are found to affect, more or less exclusively, certain well-defined districts of country; as in the case of the Guinea-worm, the Egyptian ophthalmia, the pellagra of Lombardy, the beri-beri of Ceylon and the Malabar coast, and the elephantiasis of the Indian peninsula generally. The best works on medical geography are those of Müllry in Germany, and Boudet in France, which are remarkably learned and complete treatises on the whole subject. A more recent one still is that of Dr August Hirsch of Danzig, a work of immense labour and erudition, not yet completed. On tropical diseases generally, the English works of Annesley, Twining, Morehead, and Sir Randal Martin are of confirmed reputation.

GEOLOGY (Gr. *ge* and *logos*), the science of the earth, should include all the sciences that treat of the constitution and distribution of the inorganic matter of the earth, as well as those which describe the living beings that inhabit it; just as astronomy includes the whole science of the heavenly bodies. In this wide sense, as comprising all the physical sciences, it has sometimes been used. As usually employed, however, it has a much more limited meaning, being confined to that section of the sciences which takes cognizance of the hard crust of the earth—of the materials of which it is composed, and of the manner in which these materials are arranged.

The structure of the earth received little attention from the ancients: the extent of its surface known was limited, and the changes upon it were neither so speedy nor violent as to excite special attention. The only opinions deserving to be noticed, that have come down to us, are those of Pythagoras and Strabo. They both observed the phenomena which were then altering the surface of the earth, and proposed theories for explaining the changes that had taken place in geological time. The first held that, in addition to volcanic action, the change in the level of sea and land was owing to the retreating of the sea; while the other maintained that the land changed its level, and not the sea, and that such changes happened more easily to the land below the sea because of its humidity.

From the fall of the Roman empire, during the dark ages, the cultivation of the physical sciences was neglected. In the 10th c., Avicenna, Omar, and

other Arabian writers, commented on the works of the Romans, but added little of their own.

Geological phenomena attracted attention in Italy in the 16th c., the absorbing question then being as to the nature of fossils. On the one side, it was held that they were the results of the fermentation of fatty matter, or of terrestrial exhalations, or of the influence of the heavenly bodies, or that they were mere earthy concretions or sports of nature; while only a few maintained that they were the remains of animals. Two centuries elapsed before this opinion was generally adopted. At the outset, it was unfortunately linked to the belief that the fossils were relics of the Noachian deluge.

Steno (1669) observed a succession in the strata, and asserted that there were rocks older than the fossiliferous strata in which no organic remains occur; he also distinguished between marine and fluviatile formations. He was not able, however, to free himself from the absurd hypotheses of his day.

In England, the diluvialists were busy framing idle theories, to give a plausibility to their creed, that the Noachian deluge was the cause of all the past changes on the earth's surface. Differing somewhat in detail, they all agreed in the notion of an interior abyss, whence the waters rushed, breaking up and bursting through the crust of the earth, to cover its surface, and whither, after the deluge, they returned again. Such absurd dreams, obviously opposed to the observed order of nature, greatly hindered the progress of true science.

Leibnitz (1680) proposed the bold theory, that the earth was originally in a molten state from heat, and that the primary rocks were formed by the cooling of the surface, which also produced the primeval ocean, by condensing the surrounding vapours. The sedimentary strata resulted from the subsiding of the waters that had been put in motion from the collapse of the crust on the contracting nucleus. This process was several times repeated, until at last an equilibrium was established.

Hooke (1688) and Ray (1690), differing as much from Burnet as from Leibnitz, advocated views similar to those of Pythagoras. They considered the essential condition of the globe to be one of change, and that the forces now in action would, if allowed sufficient time, produce changes as great as those of geological date. They were followed in the same direction by Vallisneri (1720), Moro (1740), Buffon (1749), Lehman (1756), and Fuchsel (1773), each contributing something additional. Werner (1780) greatly advanced the science by establishing the superposition of certain groups, by giving a system and names, and by shewing the practical applications of geology to mining, agriculture, and medicine. He had very crude notions regarding the origin of the strata, supposing that the various formations were precipitated over the earth in succession from a chaotic fluid; even the igneous rocks he held to be chemical precipitates from the waters. Hutton (1788), rejecting all theories as to the beginning of the world, returned to the opinions of Pythagoras and Ray. He held that the strata which now compose the continents were once beneath the sea, and were formed out of the waste of pre-existing continents by the action of the same forces which are now destroying even the hardest rocks. He introduced the notion of a periodical elevation of the sedimentary deposits from the internal heat raising the bed of the sea. Lyell, in our own day, has adopted and improved these views, eliminating the baseless theories which were mixed up with them, and demonstrating that existing forces might produce all the phenomena of geology.

The determination of the order of the strata, and the grouping of them in chronological order, were begun by Lehman (1756), and carried on by Fuchsel (1773), Pallas (1785), and Werner. Smith made the most important contribution to this subject when, in 1790, he published his *Tabular View of the British Strata*. He shewed their superposition, and characterised the different groups by their peculiar fossils. The publication of his Geological Map of England (1815) may be said to form an epoch in the history of geology. Since then, the science has advanced by rapid strides; and it is not too much to expect that ere long all the chief geological features of the accessible parts of the world will be known and published.

Geology, in its restricted and usual sense, takes cognizance of the solid substance of the earth, or rather of as much of it as is accessible to man's observation. He has not, by his own efforts, penetrated at any point more than a few hundred yards from the surface; but natural sections, and the peculiar arrangement of the stratified rocks (the key to which he has to some extent obtained), have given him an acquaintance with a greater thickness than could have resulted from his own labours. He has thus by actual observations, coupled with reasonings upon them, been able to construct an ideal section representing a depth of perhaps ten miles, or about a 400th part of the distance from the surface to the centre. He does not, and cannot with certainty, know anything of the structure or condition of what is deeper. This does not, however, prevent the attempt to know something of what is beyond; and in making the attempt, there are many facts which serve as bases for inductions, or at least theorisings, as to the condition of the interior of the globe. As the conclusions depend upon the balancing of evidence, upon the value given to one set of facts as set against another, they will differ according to the importance given by each individual to the one or other set of facts.

The long entertained opinion of the existence of a central heat seems to be on the whole fairly established, and upon such facts as these: 1. There is a regular and gradual increase in the temperature of all deep mines, equal to 1° F. for every 55 feet of descent after the first 100. 2. Deep wells have always a high temperature. This has been carefully determined in artesian wells, not only by applying the thermometer to the water at the surface which has risen from a known depth, but also by sinking the instrument to various depths. The results have shewn an increment similar to that exhibited in mines. Hot or boiling natural springs rise through great and deep fissures. 3. Igneous rocks—that is to say rocks which have cooled from a state of fusion by heat—invariably come from below upwards, and thus testify to an amount of internal heat able either to retain these rocks in a state of fusion, or to convert them into a fluid condition before their ejection. 4. Physics also contributes important evidence. The specific gravity of granite or basalt is scarcely 3, while that of the earth, according to the recent experiments of Airy, is about 6½. If the earth were solid, the influence of gravitation would so increase the density of the composing rock as to give a greater specific gravity for the earth than 6½. There must, then, be some expansive force acting to reduce the gravity, and the only force with which we are acquainted that could so act is heat. On the other hand, physics raises difficulties which militate against the fluid condition of any considerable portion of the earth's interior, and in these difficulties it is supported by astronomy. If, however, the observations made in mines and wells supply a measure for estimating the increase from

the surface downwards of that heat which seems to be fairly established, then it would follow that the solid crust of the earth is not more than 25 miles thick, for the heat at that depth would be so great as to fuse any known substance.

The strict province of geology is the observed or observable portion of the earth's crust. The early geologists were no more than geognosts—they observed and described the rock-mineralogy of districts, and thus laid the foundations for those generalisations which have raised geology to its present position. The materials of the earth's crust were at first grouped together according to their composition, structure, and origin; but gradually it became evident that the rocks themselves occurred in groups, and that they had a particular order in nature; until at last, all the sedimentary strata were arranged in a single continuous and chronological series, from characters drawn less from their lithological structure than from their organic contents. Both systems of classification are important—that of the geognost as well as that of the modern geologist. The one is the result, to a large extent, of work in the laboratory and the study, and may be accomplished by the examination of hand specimens; the other must be determined in the field, and only from the examination of rocks in the mass, and in their natural position. The term lithology has been applied to the one aspect, while stromatology (*strōma*, a layer) may with equal fitness be given to the other.

Lithology.—All rocks are either igneous or sedimentary; that is, have either been produced by the action of heat, or been arranged by mechanical or other means in layers or beds.

1. The Igneous rocks differ amongst themselves in their composition, structure, and age: they are made up of different materials; they have various textures, as granular, compact, or glassy; and they have been ejected at different periods of the earth's history. From these characteristics, they have been grouped thus: 1. The Volcanic Rocks (q. v.), comprising all that have been formed during the present and tertiary periods, and which are popularly known as lavas and volcanic ash. They have been ejected from volcanoes either in a fluid state, spreading over the land, and cooling as compact lavas; or spreading below shallow water, and becoming vesicular pumice, or as ash scattered in layers over the country; or they have risen into cracks and crevices of rocks as dykes and veins. Their principal constituents are felspar and augite, and the different varieties depend on the predominance of the one or other of these ingredients. The feldspathic lavas are generally light-coloured, and have a rough prickly feel to the finger. The chief varieties are Trachyte, Pearlstone, Phonolite, Obsidian, and Pumice. The augitic lavas are of a dark-green or black colour, weathering brown externally, and are generally heavier than the feldspathic lavas. The most common forms are Dolerite, Basalt, and Leucite. 2. The Trappean Rocks (q. v.), which generally belong to the primary and secondary strata, and are composed of the same materials as the volcanic rocks, except that the silicates of magnesia and lime crystallise in the latter as augite, while they assume the more obtuse form of hornblende in the trappean rocks. Trap-rocks are always associated with a pipe or dyke connecting them with the underlying mass from which the materials were obtained. They have either overflowed the surface, and formed a bed conformable to, and contemporaneous with the subjacent strata, or inserted themselves between already formed strata, forming injected sheets that are not contemporaneous. The predominance of the one constituent

material over the other gives the basis for grouping the trappean rocks into the feldspathic traps, which are light-coloured and generally compact rocks, the chief varieties being Felstone and Fitchstone, and Hornblendic traps or Greenstones, containing the most abundant and best known rocks of this division. They are of a greenish colour, varying from very light, when the felspar is white and abounding, to almost black, when the constituent minerals are finely divided and coloured with iron. In texture, also, there is considerable difference, some being fine-grained and compact, while in others the crystalline structure is very evident. The principal varieties are Greenstone, Basalt, and Melaphyre. Porphyry occurs in both the volcanic and trappean rocks when the felspar is aggregated in large and evident crystals, scattered through the body of the rock. 3. The Granitic Rocks (q. v.). The striking characteristic of these rocks is the abundance of siliceous in a separate and uncombined state as pure quartz. Granites are associated with the primary strata; they form also the support of the sedimentary deposit, wherever their base has been exposed to view. They occur in beds overspreading the sedimentary deposits or intercalated with them, in dykes, or as the apparent fundamental and unstratified rock. The chief varieties are true Granite, Syenite, and Protogene.

II. The Sedimentary Rocks occur in layers or strata. They are either aqueous, aerial, chemical, or organic in their origin. 1. The Aqueous Rocks (q. v.) are Argillaceous (q. v.), composed more or less of clay, as kaolin shale and clay-slate; or Arenaceous (q. v.), in which the constituent portions are so large as to be evident to the eye, as in sandstone. The aqueous rocks were deposited in thin layers, which, however, frequently cohere, so as to form solid masses or beds of considerable thickness. Originally deposited horizontally, they have in many cases been subjected to disturbances that have elevated or depressed them; hence have arisen Faults (q. v.) and Dislocations (q. v.), as well as the exposing of the edges of the strata on the surface of the earth (Strike, q. v.) at various angles (Dip, q. v.). 2. The Aërial Rocks, which cannot be easily separated from aqueous rocks, except by their anomalous stratification (see Drift). They play so important a part on sandy coasts and arid interiors at the present day, that it cannot be doubted that they helped in former periods to bring the earth into its present condition. 3. The Chemical Rocks have been formed from the evaporation of liquids containing substances in solution. The materials thus deposited are salt, gypsum, lime, and siliceous. Salt is generally associated with gypsum, and occurs in a great range of formations from the Devonian or Carboniferous, up to the most recent. The salt mines at Northwich, in Cheshire, belong to the Triassic period. Rock-salt occurs in a coarsely crystalline mass, generally coloured with iron, and more or less mixed with clay and other impurities. The deposits are often of great thickness, but apparently of limited extent, and were probably precipitated in isolated brine-lakes. Gypsum seems to have been formed under similar circumstances. It is abundant in the Magnesian Limestone, in the London Clay, and in the Paris Basin. Lime has not been deposited in masses, like gypsum, but only from the exposure to the atmosphere of small quantities of liquid saturated with it, which, by evaporation, have left stalagmitic or tufaceous deposits. Siliceous sinter has been deposited in a similar manner as it is at the present day around the hot springs of Iceland. 4. The Organic Rocks are those which have been entirely, or to a large extent, formed from the remains of animals—as chalk and other more

compact limestones—or vegetables, as coal, lignite, and diatomaceous deposits.

Changes are continually taking place in the sedimentary rocks, altering their structure and texture. Among the chief agents including these metamorphic changes are chemical attraction, the infiltration of water, the pressure of the superincumbent strata, and above all, heat and magnetism. Some of the older strata have been so much altered that they are generally spoken of as Metamorphic Rocks (q. v.).

Stromatology.—We apply this title to that division of geology which considers the stratified rocks in their chronological order, as exhibiting different phases of the history and development of the globe itself, and in their fossil contents setting forth the progress of life upon its surface. Referring to the article PALÆONTOLOGY for a notice of the animal and vegetable organisms that have been preserved in the rocks, we shall here give a rapid sketch of the various periods in the earth's geological history.

The original, and, as it is supposed, molten condition of the globe is hid in mystery and uncertainty. The geologist takes up the history at the point where air and water make their appearance, and where the inorganic substances were subject to the same influences as those now in operation. It is very doubtful whether the fundamental crust is in any place exposed or has ever been uncovered by man. The earliest rocks observed, though probably not the oldest, are those described by Logan as the *Laurentian System* (q. v.). The typical beds occur in Canada; strata of the same age have lately been detected in Scotland by Murchison and Geikie. The strata have been very much metamorphosed by the action of heat, and by the many chemical and physical forces which heat has set in motion, so that the original condition is entirely altered, the whole series being converted into gneissose strata, with one or two greatly altered beds of limestone. Fossils, if they ever existed, have been obliterated. Even in the succeeding *Cambrian Series* (q. v.), they are very rare, consisting of a few zoophytes, crustaceans, and annelids, with very doubtful impressions of sea-weeds. The rocks of this period consist of thick masses of sandstones and slates or shales. The *Silurian Period* (q. v.) is represented by immense marine deposits, which in some districts are rich in the remains of invertebrate animals, while other extensive tracts have not yielded a single fossil. No certain evidence of plants has yet been observed in this period, yet the economy of life would however require then, as now, oxygen-producers and carbonic acid consumers. Perhaps the anthracite of the graptolitic shales, and the oil from the bituminous Silurian shales of North America, may be in part or in whole of vegetable origin. The first traces of the existence of dry land occur in the *Old Red Sandstone* (q. v.). The great mass of the strata of this period consist of immense thicknesses of limestone, composed of corals and shell-fish, of beds of shale and of sandstone, crowded in some places with fish-remains. A few land-plants and air-breathing animals, the tenants of the dry land, are preserved in the upper strata, which, however, probably belong to the next period. The *Carboniferous Measures* (see CARBONIFEROUS SYSTEM) are ushered in by a great thickness of deep-sea limestone. The coal-bearing strata are alternately sea, estuary, or lake deposits of sandstone, shale, and limestone, and dry land surfaces with the vegetation converted into coal. The waters teemed with fishes of great size and strange form; and the dry land was covered with a rank and luxuriant vegetation of ferns and coniferous trees, and strange forms like gigantic reeds and club-mosses. A few air-breathing reptiles and shells have been

GEOMANCY—GEOMETRICAL PROGRESSION.

found in these strata. The *Permian Period* (q. v.) exhibits a group of organisms differing little from those of the preceding epoch, with the exception of a few added reptiles. The Permian strata are sandstones, gypseous marls, and common and magnesian limestones.

With these beds terminate the Palaeozoic Rocks. Before the commencement of the Secondary Epoch, great disturbances and depressions took place in the districts whose geological structure has been examined; and at the same time a great change took place in the character of the animal and vegetable life.

The typical rocks of the *Triassic Period* (q. v.), the earliest of the Secondary Epoch, exist in Germany. They are highly fossiliferous, containing the remains of marine animals of various kinds. In Britain, the rocks are chiefly red sandstones and red marls, the colouring matter of which seems to have been destructive to life; the only fossils they contain are a few land-plants, and some footprints and fragments of bones of reptiles.

The *Lias* (q. v.), which follows, and forms the base of the Oolite formation, consists of extensive clay deposits, with argillaceous limestones and sandstones—strata which indicate the existence of large tracts of land. The contained fossils have a mixed land, fresh-water, and sea character. With considerable numbers of plants and insects, there are also marine brachiopods and cephalopods, and the remarkable swimming reptiles, that are so perfectly preserved as to supply materials for nearly perfect restorations.

The *Oolite Series* (q. v.) consists of alternating beds of limestone and clay, with very little intervening sandstone. The abundance of dry land is testified to by the number and variety of the air-breathing fossils (amongst which mammalia appear for the first time), and even by the occurrence of strata that have been ancient soils. The group is highly fossiliferous.

The *Cretaceous Strata* (see CRETACEOUS GROUP), which, as a whole, have had a deep-sea origin, are introduced by fresh-water and estuary deposits, shewing that great tracts of land were traversed by mighty rivers actively abrading and carrying off materials for delta deposits. The life of the period was abundant. The immense thicknesses of chalk, which give the name to the group, are composed to a very large extent of the perfect or comminuted shells of foraminifera and mollusca. Besides these, land-plants, fresh-water, and marine shells and fish, and large terrestrial and marine reptiles, occur. Birds and mammalia have not yet been observed, but it is most probable that they did exist, as they have been found in older strata.

In passing to the Tertiary Epoch, there is not found so striking a change in the life of the globe as that which characterised the division between the Palaeozoic and Secondary strata. From the Trias, the fossils have been gradually assuming the appearance of existing organisms: many strange forms have existed and passed away without leaving representatives in the later strata or in the living inhabitants of the earth. Still, the *facies* of the organic remains gradually approaches that of the present fauna and flora, until the *Eocene Period* (q. v.), when some fossils appear, which, if not identical with recent species, so nearly approach them, as to make it impossible to distinguish them. The proportion of such species is from $3\frac{1}{4}$ to 5 per cent. The seas in which the Eocene beds were deposited were comparatively small, and consequently the deposits occur in scattered and isolated basins. The earlier strata are marine, but towards the middle of this period they become lacustrine or fluvial.

The *Miocene Period* (q. v.) is said to contain above 25 per cent. of living forms. It is doubtful whether there are in Britain any true representatives of this period. The strata are largely developed in France and Belgium. Besides abounding in marine mollusca, the Miocene strata contain the remains of many large mammalia. The deposits of the *Pliocene Period* (q. v.) contain from 50 to 70 per cent of existing forms. The strata are marly sands and gravels abounding with sea-spoils.

In the *Pleistocene Strata* (q. v.), the proportion of existing forms is still greater—indeed, all the principal generic forms now alive, except man, seem to have been in existence during this period. The strata consist of the sands, gravels, and boulder clay left by glaciers and icebergs, of marls and raised sea-beaches.

The newer strata belong to the human period, and have been, and are continuing to be, formed by agents now in operation. They contain the remains of species of plants and animals which still live on the globe.

GEOMANCY. See DIVINATION.

GEOMETRICAL, related to Geometry (q. v.), as a geometrical line, demonstration, construction, &c. As to geometrical lines, see CO-ORDINATE, CURVES, and DEMONSTRATION. Geometrical constructions and solutions were anciently such as were effected by means of the straight line and circle—the only lines which were regarded as properly geometrical—and according to the strict rules of geometry. The ancient geometers employed two methods of reasoning in their inquiries and demonstrations, known as *geometrical analysis* and *synthesis*. Of these, the synthetical method was the older and more generally employed. It is abundantly illustrated in Euclid's *Elements*, in which new truths are deduced from combinations of truths already established, so that every proposition depends on others preceding it. See SYNTHESIS. Though admirably suited for the demonstration of truth once ascertained, this method was found of little use in the discovery of truth, or of the mode of its demonstration. For these purposes, the analytical method is admirably adapted. See ANALYSIS. According to this method, the proposition which is to be proved is assumed to be true, or the construction required is supposed to be effected; and then the conditions of the proposition being true, or the construction effected, are investigated by reasoning backwards till some elementary truth or simple construction is reached, on which the truth or construction under inquiry is seen to depend. The analytical method of reasoning in geometry is said to have been invented by Plato. The Greeks have left on record many proofs of the power and beauty of the method as a means of discovery.

GEOMETRICAL MEAN of two numbers is that number the square of which is equal to the product of the two numbers; thus, the geometrical mean of 9 and 16 is 12, for $9 \times 16 = 144 = 12^2$; hence the geometrical mean of two numbers is found by multiplying the two numbers together, and extracting the square root of the product.

GEOMETRICAL PROGRESSION. A series of quantities are said to be in geometrical progression when each term of the series is equal to that which precedes it multiplied by some constant factor—i. e., some factor which is the same for all the terms; or, in other words, when the ratio of any two successive terms is the same. Thus $a, ar, ar^2, ar^3 \dots$ and $2, 6, 18, 54 \dots$ are geometrical series. The sum of n terms of the former series may be easily obtained. Let it be S . Then $S = a + ar + ar^2 + \dots + ar^{n-1}$. Multiply both

sides by r , we have $rS = ar + ar^2 + \dots + ar^n$. Subtracting the former of these expressions from the latter, we have $(r-1)S = ar^n - a$. Whence we have $S = a \cdot \frac{r^n - 1}{r - 1}$. If the series be one whose terms constantly diminish, i.e., if $r < 1$, and then if we suppose n indefinitely great, r^n will be indefinitely small, and we shall have $S = \frac{a}{1-r}$ for the sum of the series extended *ad infinitum*. For example, the sum of the series $\frac{3}{10} + \frac{3}{10^2} + \frac{3}{10^3} + \dots$ *ad infinitum* is $\frac{1}{2}$. It is obvious that any three of the four quantities a , r , n , S being given, the equation $S = a \cdot \frac{r^n - 1}{r - 1}$ will enable us to find the fourth.

GEOMETRICAL TRACERY, a name frequently used to distinguish a class of tracery where the parts are all more or less like diagrams in geometry. See **TRACERY**.

GEOMETRY, the science of space, discusses and investigates the properties of definite portions of space under the fourfold division of lines, angles, surfaces, and volumes, without regard to any physical properties which they may have. It has various divisions, e.g., Plane and Solid Geometry, Analytical or Algebraical Geometry, Descriptive Geometry, and the Higher Geometry. Plane and solid geometry are occupied with the consideration of right lines and plane surfaces, and with the solids generated by them, as well as with the properties of the circle, and, it may be said, the sphere; while the higher geometry considers the conic sections and curved lines generally, and the bodies generated by them. In the higher geometry, immense advances have recently been made through improved methods, the application of modern analysis, and the various calculi in algebraical geometry, the nature of which is explained in the article **CO-ORDINATES** (q.v.). Descriptive geometry, a division of the science so named by Monge (q.v.); is properly an extension or general application of the principle of Projections (q.v.), its object being to represent on two plane surfaces the elements and character of any solid figure. It has many practical applications. When one surface penetrates another, for instance, there often result from their intersection curves of double curvature, the description of which is necessary in some of the arts, as in groined vault-work, and in cutting arch-stones, &c., and this is supplied by descriptive geometry.

The history of geometry is full of interest, but no more can be given here than a very bare sketch of it. The name of the science (Gr. and Lat. *geometria*) originally signified the art of measuring land. Herodotus, the earliest authority on the subject, assigns the origin of the art to the necessity of measuring lands in Egypt for the purposes of taxation, in the reign of Sesostris, about 1416—1357 B.C. (Hero, book ii. chap. 109). This is probable, not only as resting on such authority, but also because, *a priori*, we should expect the necessity of measuring lands to arise with property in land, and to give birth to the art. Of the state of the science, however, among the Chaldeans and Egyptians, we have no record.

The story of Herodotus is further confirmed by tradition. Proclus, in his commentary on Euclid's *Elements* (b. ii. c. 4), says that the art was brought to Greece from Egypt by Thales, who was himself a great discoverer in geometry. The Greeks at once took keenly to the study; various disciples of Thales excelled in it, chief among them Pythagoras, who, according to Proclus, first gave geometry the

form of a deductive science, besides discovering some of its most important elementary propositions, among others, it is said, the 47th Prop. *Eucl. b. i.* See article **PYTHAGORAS** for a notice of his other contributions to the science. Pythagoras had illustrious successors: Anaxagoras of Clazomenæ; Anopidia, the reputed discoverer of *Eucl. b. I. 12, 23*; Briso and Antipho; Hippocrates of Chios, who 'doubled the cube,' and quadrated the lunula, which bear his name, and is said to have written a treatise on geometry; Zenodorus; Democritus of Abdera; and Theodorus of Cyrene, who is said to have been one of the instructors of Plato, whose name marks an epoch in the history of the science. Over his Academy at Athens, Plato placed the celebrated inscription, *Μοδεὶς ἀγεμετρεῖος εἰσιτο* ('Let no one ignorant of geometry enter here'), thus recognising it as the first of the sciences, and as the proper introduction to the higher philosophy. He is the reputed inventor of the method of geometrical analysis, and of geometrical loci and the conic sections, called in his time the higher geometry. From his Academy proceeded many who advanced the science, of whom Proclus mentions thirteen, and more than one of them as having written treatises on the subject, that have been lost. We shall mention but two of these: Eudoxus, who is said to have brought into form and order in a treatise the results of the studies at the Academy, and to have invented the doctrine of proportion, as treated in the 5th book of Euclid's *Elements*; and the great Aristotle, who assigned geometry as high a place as Plato did, and who wrote a treatise on the subject, as did at least two of his pupils, Theophrastus and Eudemus, from the latter of whom Proclus took most of his facts. Autolycus, a disciple of this Theophrastus, wrote a treatise on the movable sphere, yet extant; while Aristæus, the reputed instructor of Euclid in geometry, is said to have written five books on the conic sections, and five on solid loci, all of which are lost.

The name of Euclid marks another epoch in the history of geometry, and the chief interest of the vague sketch above given of the labours of his predecessors lies in its demonstrating the great mass of materials from which he constructed his *Elements*—the variety of treatises which prepared the way for that great work whose pre-eminence has now for over 2000 years been undisputed. In the *Elements*, Euclid collected all the theorems which had been invented by his predecessors in Egypt and Greece, and digested them into fifteen books, demonstrating and arranging the whole in a very accurate and perfect manner. See **EUCLID**. Next to Euclid, of the ancient writers whose works are extant, must be named Apollonius Pergæus, who flourished about 230 B.C., and about 100 years later than Euclid, and was called 'the Great Geometrician,' on account of his work on the Conics, and other ingenious geometrical writings. Much about the same time with Apollonius flourished Archimedes, not less celebrated for his geometrical than for his mechanical inventions. See **ARCHIMEDES**, and **APOLLONIUS OF PERGÆA**. It may be mentioned that Apollonius first gave the names of *ellipse* and *hyperbola* to two of the conic sections, the third of which had previously been called the *parabola* by Archimedes.

For a long period after the time of Archimedes, we find few names of note in connection with geometry. We but mention Nicomedes, Hipparchus, and Theodosius of Tripoli. The Greeks, however, never intermitted their attention to the science; they continued it even after their subjugation by the Romans, and we find them producing many excellent geometers after the translation of

the Roman Empire, and within our era: Ptolemy (q. v.), who died 147 A.D.; Pappus (q. v.), who lived in the time of Theodosius (379—395 A.D.); Proclus, who lived in the 5th, and Eutocius, in the 6th century. The works of all these writers are still extant. Meantime, the Romans, the dominant race, even in the most flourishing time of the republic, were so ignorant of the science, that, according to Tacitus, they gave the name of Mathematicians (q. v.) to those who practised divination and judicial astrology. As may be supposed, their domination was not favourable to the science, and only one Roman name can be mentioned—viz., Boëthius, who lived towards the close of the 5th c., who attained eminence in geometry; and of his writings, it must be said, as of the Roman literature generally, that they were but compilations and reflections of Greek thought. But if the Roman empire was unfavourable, its downfall, and the consequent inundation of ignorance and barbarism, were still more so. The rise of the Mohammedan power in the 7th c., and the rapid and desolating consequences which followed, further hastened the extinction of the Greek sciences. The time now came when those who devoted themselves to science were everywhere branded as magicians, and exposed to popular fury. It was in these times that, fortunately for civilisation, an asylum was found for the spirit of inquiry in Arabia. An acquaintance with the science of the Hindus prepared the Arabians for the reception of the writings of the Greek astronomers and mathematicians; and the dispersion of the scientific coteries of Alexandria gave to Bagdad many preceptors in the learning of the West. In little more than a century after it took place, the Arabians were the most zealous patrons and cultivators of Greek science; from the 9th to the 14th centuries, they produced many astronomers, geometricians, &c.; and through them the mathematical sciences were again restored to Europe towards the close of the 14th c., being first received in Spain and Italy. The revival of ancient literature in Europe, and the discovery of the art of printing about the middle of the 15th c., concurred to diffuse a knowledge of the science of the Greeks, which came into notice with their general literature; and from this date, many names occur of eminent geometricians. During the 16th c., Euclid was held in such estimation, that no attempts were made to advance the science beyond the point at which he left it. Commentaries and translations of the *Elements* of Euclid were rife; but till the time of Kepler, no attempts were made to improve or extend the methods of geometry. Kepler (q. v.) introduced the principle of infinity into geometry. Next, Descartes, seizing the results of Vieta's discoveries in the use of symbols, invented the new or the analytical algebraical geometry, which vastly extended the domains of the science. It then required but the invention of the calculus to give the science that grand sweep and power which it now possesses. For a notice of some of the more recent improvements in geometrical methods, see TRANSVERSAIS, POLARS, PROJECTIONS. The reader will also find a very excellent view of the growth of the science in the introduction to Mr Pott's *Euclid* (London, 1845); also under the various names of those mentioned in this article, will be found fuller notices of their contributions to the science. No full list can be given of the contributors, but it would be unjust not to refer here to Johann Müller (called Regiomontanus), Copernicus, Tartaglia, Vieta, Galileo, Fermat, Roberval, Pascal, Huyghens, Barrow, Newton, the Gregories, Lagrange, Clairaut, Euler, Robert Simson—whose translation of Euclid may be regarded as the standard text in English—Mathew Stewart,

Brook Taylor, Maclaurin, Monge, Poncelet, Carnot, Chales, and Sir William Hamilton of Dublin. See also QUATERNIONS.

GEORGE I., king of Great Britain, son of Ernst August, Elector of Brunswick, and of Sophia, a granddaughter of James I. of England, was born on 28th May 1660. According to the theory that the blood of James II. in the direct line was 'corrupted,' he was the nearest heir to the crown. On the death of Queen Anne, 31st July 1714, he was instantly proclaimed king, and arrived in this country from his electorate of Hanover at the age of 54. To him this country was to the last a foreign country, for which he had no love, and of the language, feelings, and thought of which, he was profoundly ignorant. His affections remained with Hanover, but to Britain his alliances, experience, and fair abilities for business, resolutely exercised, were of considerable value. A king of more brilliant parts might have been an impediment in the way of constitutional government adjusting itself to habits of domestic peace and order after the dethronement of the Stuarts, whose ruined fortunes excited the pity of the people, and afforded a convenient cry for the minority, that declaimed in private, and wrote songs, and plotted against the imported king, whom they called a 'foreign tyrant.' Being supported by the Whigs, and undisguisedly partial to them, the Tories were adverse to him, as well as the Jacobites, and they associated together to bring about a revolution. In Scotland, in 1715, the Earl of Mar raised the standard of rebellion; and he had collected about 10,000 men, when he engaged the Duke of Argyle with about half that number of men at Sheriffmuir, near Dunblane. It was a drawn battle, the left wing of both armies being victorious; but to the rebels it was not a victory, and it caused delay and checked their progress, and that was equivalent to a defeat, for the Highlanders, seeing little prospect of fighting and plunder, returned home; and in that part of the island the rebellion may be said to have burned out of itself. In England, it did not succeed so well; and it was ended miserably by the unconditional surrender of the insurgents at Preston. For this outbreak the Earl of Derwentwater and Viscount Kenmore were beheaded on Tower Hill, several officers were shot, many persons of distinction were attainted, about thirty of the less conspicuous rebels were executed, and above 1000 were transported to the plantations. The Earl of Mar and the Pretender both escaped to France.

The next most notable and calamitous event of this reign was the failure of the South Sea Company (q. v.). A quarrel with the Spaniards commenced in 1726, which issued in a somewhat unsuccessful expedition of Admiral Hosier to their American possessions, and a fruitless attempt on Gibraltar (q. v.) by the Spaniards. In 1727, George I., who had, amid the splendours of British royalty, sighed for his fatherland and his family, set out for Hanover, and died of apoplexy on his way to visit his brother, who was Bishop of Osnaburg, on the night of the 10th or the morning of the 11th of June. His life was not a happy one. His wife, Sophia Dorothea of Zell, to whom he was untrue, had solaced herself by yielding to the attentions of Philip von Koningsmark. On Sunday the 1st July 1694 the latter disappeared for ever in a mysterious way, and on the 28th December Sophia was divorced. The remaining 32 years of her life were spent as a prisoner in the fortress of Ahlden, where she died at the age of 60. There are clear glimpses of George I. in Carlyle's *Life of Frederick the Great*. Carlyle commends his talent for silence, and thinks him, in spite of appearances, a man of

GEORGE II.—GEORGE III.

more human faculty, 'chiefly of an inarticulate kind,' than he generally gets credit for.

GEORGE II. succeeded his father as king of England in the 45th year of his age. He was born at Hanover on the 30th October 1683, and married Carolina Wilhelmina, daughter of the markgraf of Anspach. She is said to have been a woman of uncommon attainments in literature, theology, and politics, and her death in 1737 was reckoned a public loss. The king himself did not aspire to a code of morals different from his fathers, nor to any intellectual accomplishments except those of a soldier. He was present at the battle of Dettingen in 1743, and with the assistance of the Earl of Stair he gained it: the French being entirely defeated, and very efficient service rendered to Maria Theresa of Hungary, who had besought it to prevent the partition of her dominions. His second son, the Duke of Cumberland, was not so fortunate, for the English forces under him were defeated with great loss in 1745 at Fontenoy by the French under the famous Marshal Saxe. In the same year (1745) Prince Charles Stuart, son of the old Pretender, landed in Scotland with seven officers, and arms for 2000 men. After some transient successes, he was completely defeated at Culloden, 16th April 1746, and what is known as the *Second Rebellion* was brought to an end. (See STUART, CHARLES EDWARD.) The Duke of Cumberland, whose barbarities in the suppression of the insurrection earned him the name of the 'Bloody Butcher,' returned to the command of the English forces on the continent, and was repeatedly beaten by Marshal Saxe and the French; much that Marlborough had gained being lost. In India, Colonel, afterwards Lord Clive, gained various victories, the chief of them being the victory at Plassey in 1756, which laid the foundations of the British East Indian Empire; and during the next three years the British dominion in North America was extended and strengthened by the victory of Wolfe on the heights of Abraham, and by the subsequent surrender of Quebec. British allied troops contributed to the Hanoverian victory at Minden in 1739. G. died 25th October 1760, in the 77th year of his age, and the 34th of his reign. Generally, the reign of George II. was a prosperous one: according to Hallam, 'the most prosperous period that England had ever known;' and it was this not less from the acquisition of new territory, than from the conquest of new fields of thought effected by Pope, Hume, Samuel Johnson, Fielding, Smollett, Reynolds, Hogarth, and many others.

GEORGE III., son of Frederick Lewis, Prince of Wales, succeeded his grandfather, George II. He was born on the 4th June 1733, and died at Windsor Castle, on the 29th January 1820, in the 60th year of his reign, which was eventful as well as long. On 8th September 1761, he married the Princess Charlotte Sophia, daughter of Charles Duke of Mecklenburg-Strelitz, and was by her the father of fifteen children. His intellect was not of the strongest, but, like his two predecessors, he had firmness of purpose, and, in addition, a conscientiousness and sense of decorum unknown to them, while both friends and enemies could rely upon him—the one for favours, and the other for the reverse. His mind gave way several times—in 1764, in 1788, in 1801, in 1804; and in 1810, when the British were fighting behind the lines of Torres Vedras, his final insanity supervened. He had an abundance of cares, like most sovereigns. The *Letters of Junius* and the invectives of Wilkes annoyed him; so did the proposals to emancipate the Roman Catholics, and the terrible French

Revolution of 1789. His life was attempted by the maniacs Margaret Nicolson and a man named Hatfield. The marriages of two of his brothers with the widows of subjects displeased him, and led to the passing of the Royal Marriage Bill, 12 Geo. III. c. 11, prohibiting the members of the royal family from contracting marriage without the consent of the king, if under twenty-five years of age, and the consent of parliament if above that age; and afterwards the undoubted debts and dissipation of his eldest son, who became George IV., his hardly doubtful marriage with Mrs Fitzherbert, the Roman Catholic widow of two husbands, and the scandals of his public marriage with his cousin, Caroline of Brunswick, must have led the 'good old king' to reflect that not even a 'marriage-bill' could cure all the domestic miseries of monarchs. Nor were matters of national excitement and magnitude wanting. A bill, imposing certain stamp-duties upon the American colonies, which had been resolved to be inexpedient in 1764, was passed in March 1765, and repealed in 1766 by the Marquis of Rockingham's ministry; and in 1767 the chancellor of the exchequer, Mr Townshend, brought forward a plan for the taxation of these colonies, which led to their revolt, the colonists objecting to be taxed by a parliament in which they were not represented. In 1770, Lord North, the premier, brought in a bill for the repeal of all the recently imposed American duties, except the duty on tea, which was retained, to assert the English right to impose taxes on these colonies. In December 1773, 'Boston harbour is black with unexpected tea,' cargoes of it being wantonly destroyed by the colonists; and on 19th April 1775, hostilities commenced with the undecided battle of Lexington, which on the 16th June was followed by that of Bunker's Hill, which was a victory to the colonists, and helped to give them boldness to renounce the dominion of Great Britain, and publish the declaration of independence on the 4th July 1776. George Washington, a colonel of militia, who had been appointed general of the insurgent colonists, took possession of Boston in that year, having compelled General Howe and the British troops to retire, and next year he gained an important advantage by the capture of Burgoyne's army of 10,000 fine troops, British and German. The French, Spanish, and Dutch all threw their weight into the American scale, and the chequered and disastrous struggle ended in America by the surrender of Lord Cornwallis, with a British army of 6000, to Washington and the Marquis de la Fayette. The French suffered at sea by the gallantry of the British under Byron, Hood, and Rodney, this last having, in 1782, in the West Indies, obtained over them a naval victory by the hitherto untried method of breaking the enemy's line. In that year, also, General Elliott repulsed the grand attack of the French and Spaniards, and put an end to their chances of success in the obdurate siege of Gibraltar. At Versailles, on 3d September 1783, a peace was concluded with France and Spain, in which the independence of the American states was recognised, not a little to the satisfaction of many of the English at home, who, besides being tired of the struggle, had throughout the contest sympathised with the American colonists, whose cause, originally good, had had its merits kept before the public mind by the eloquence of Chatham, Fox, and Burke, three of the greatest orators of all time.

Meanwhile, the British rule in India was consolidated, and this was effected in no insignificant degree under the governor-generalship of Warren Hastings, a most able but somewhat unscrupulous

man His trial for misrule and oppression, famous for the eloquent accusations of Burke and Sheridan, began in 1786, and was protracted for nine years. Wars with Hyder Ali and his son Tippoo Saib were ended by the storming of Seringapatam in 1799.

The after-swell of the French revolution broke over all the continent of Europe in wave after wave of war. The aversion of Britain to the insane democracy of France was not concealed, and in 1793, a few days after the execution of their king, the French declared war against Britain. In the confused warfare that followed, the English, under Lord Howe, in 1794, defeated the French fleet in the Channel; under Sir John Jervis they defeated the Spanish fleet off Cape St Vincent in 1797; and also in that year, under Lord Duncan, they defeated the Dutch off Camperdown; and in 1798 Nelson was victorious on the Nile over the French fleet that had conveyed Napoleon Bonaparte and his troops to Egypt. In 1801, he bombarded Copenhagen, and partially destroyed the Danish fleet; and the forces under Sir Ralph Abercromby—who was mortally wounded—gained the victory of Alexandria over the troops which Napoleon had left in Egypt to menace the power of Britain in the East. On 25th March 1802, the treaty of peace of Amiens was signed, but, within a year, hostilities were renewed. In 1803, Hanover was occupied by the French. On October 21, 1805, Nelson lost his life, and gained his greatest victory of Trafalgar over the French and Spanish fleets. Napoleon's splendid victory of Austerlitz over the Austrians and Russians, December 1805, was survived only a few weeks by the great statesman Pitt, whose breaking heart and constitution could not sustain the shock of this last disappointment. Napoleon's Berlin decree of 1806, and his Milan decree of 1807, declaring the British dominions in a state of blockade on purpose to destroy British commerce, were not supported by a sufficient navy to carry them into execution by capturing vessels trading with Britain; but they did no inconsiderable damage. In 1808, Sir Arthur Wellesley landed in Portugal, and defeated the French at Vimeira; but the advantage of this victory was thrown away in the Convention of Cintra. The retreat, four months after, to Corunna of the English army under Sir John Moore, from overwhelming odds, and its safe embarkation in January 1809, after the repulse of Marshal Soult, has secured a reputation for the able and distinguished general who fell there hardly inferior to that of those who have died in the moment of victory. In April of that year, Sir Arthur Wellesley returned to the command in the Peninsula, and after conquering at Talavera on the 8th of July, wearing out the powers of the assailing French behind the lines of Torres Vedras during the last months of 1810, and conquering at Fuentes de Onoro in 1811, at Salamanca in 1812, at Vittoria in 1813 (as Lord Wellington), and in other battles and sieges, he drove the French out of the peninsula. The struggle was terminated on the eventful field of Waterloo (q. v.), 18th June 1815.

On the 1st of January 1801, Ireland was united to Great Britain, and its separate legislation was abolished. During this reign many Scotchmen had forced their way to the first places in the state; all the Jacobite feelings had died out; and the Union had become not a legislative one merely, but a union of society, literature, thought, and enterprise. The most original and vigorous thought of this period found its expression in poetry, and among its great poets, the most noteworthy are Byron, Coleridge, Wordsworth, and Walter Scott, the last of whom is also at the head of all the writers of prose-

fiction. In spite of the depressing effects of war, commerce greatly increased during the 60 years of this reign; and the revenue, which at the beginning of it was under nine millions, had, during the years of the French war, been increased more than sevenfold, thus shewing, though by an undesirable method, the vast increase of the resources of the country. Chemistry and the steam-engine were beginning to alter the face of society. Among legislative reforms, the most conspicuous was the abolition of the punishment of death for minor crimes, and generally the statute-book, which had greatly increased, became more and more favourable to individual liberty.

GEORGE IV. became king of Great Britain on his father's death. He had been virtual sovereign during the long period of his father's last insanity, as Prince Regent. He was born on 12th August 1762, and died on the 26th June 1830. That he should have lived so long as 67 years is not the least notable circumstance connected with a life that has supplied as much material for scandal as any in English history. G. had considerable intellectual ability and address, could tell stories well, and enjoy every day without thinking of the next. His personal attractions, and his position together, led many in his lifetime to style him, not without sincerity, 'the first gentleman of Europe;' but the decay of king-worship, and the growth of morality, have not allowed that to continue to be the opinion of his countrymen. His frailties, and those of his royal namesakes, have been mercilessly exposed by Thackeray in his 'Four Georges' (1861). Unfortunately for their memory, no man of Thackeray's abilities has set himself to look for their virtues and their good deeds to England—which were not few—and for which they have earned the gratitude of patriots, not mere blind worshippers of royalty.

The marriage of George IV. was specially unfortunate. He entered into it on 8th April 1794, with his cousin, Caroline Amelia Elizabeth, second daughter of the Duke of Brunswick, under the pressure of debt, and of his father, and their conjugal happiness, if it ever existed, did not last many weeks. The Princess Charlotte Augusta was born of the marriage on 7th January 1796, and shortly after her parents separated, having ceased to speak to each other months before. See CAROLINE. The Princess Charlotte had married Prince Leopold, now (1862) king of Belgium, and she died in childbirth on 6th November 1817, greatly to the grief of the whole nation.

Royal visits to Scotland and Ireland; the aid rendered to the Greeks by the British fleet in the battle of Navarino (1827), which secured the independence of Greece; and the passing (1829) of the Roman Catholic Relief Bill (q. v.) (so odious to his father), are the most notable incidents of this king's reign. He was succeeded by his brother William, Duke of Clarence, who had entered the navy in his youth.

GEORGE (the Bearded), Duke of Saxony, eldest son of Albert (the Brave), the founder of the Ducal or Albertinian Saxon line, was born in 1471. He early exhibited a strong desire for the acquisition of religious knowledge, and in 1484 was sent to Meissen to pursue his studies, with a view to his entering the church. On the death of his father in 1500, G. succeeded to the whole dukedom, consisting of the half of Thuringia and Meissen, with the exception of the lately acquired country of Friesland, which fell to his younger brother Henry; who, however, soon after exchanged it with G. for Freiberg and Wolkenstein. Though G. and William, Duke of

Lower Bavaria, were the two pillars of Catholicism in Germany, yet the former did not appear to be much displeased with the proceedings of Luther previous to the Leipsic controversy; on the contrary, they were at one in regard to the many abuses which had crept into the church, but G. wished to remedy them through papal edicts, or the decisions of a general council. The ill-feeling between G. and Luther commenced during the Leipsic controversy, and arose from a misapprehension of Luther's doctrine of justification by faith; it necessarily increased in strength in one who was so remarkable for obstinacy, especially as it was carefully fostered by John Eck and other of Luther's enemies. Yet when the emperor seemed likely to violate his safe conduct given to Luther, G. strongly protested against such a breach of good faith. The later years of his reign were embittered by a succession of domestic calamities: first his wife died, then all his children in succession, and thus his brother, Henry of Freiberg, became heir-apparent. Henry was a zealous Protestant, and such was G.'s antipathy to being succeeded by one of that religion, that he attempted to break the line of succession, but did not live long enough to accomplish his purpose. He died in 1530, and was succeeded by Henry.

GEORGE, a district of the Cape Colony, is separated from that of Zwellendam on the west by the Gauritz (q. v.). It contains 4032 square miles, and about 20,000 inhabitants. It is valuable chiefly for its pasture and its timber. On its coast is the port of Mossel Bay.

GEORGE (LAKE), called also Horicon, a picturesque sheet of water, remarkable for its transparency and for the beauty of the scenery on its shores, lies in the state of New York, and measures 34 miles by 3. It discharges its waters into Lake Champlain, thus forming a part of the grand system of the St Lawrence. It is, in some places, 400 feet deep. It possesses some historical interest in connection with the North American wars between England and France.

GEORGE (St), one of the Bermudas, is strongly fortified, and forms the principal depot in the group for military purposes. On the south coast is a town of its own name, which has a large harbour of considerable strength.

GEORGE, St, a saint, venerated both in the Eastern and Western churches, held in especial veneration as the patron of Chivalry, and adopted as the tutelary saint of England. His origin is extremely obscure; and the very oldest accounts of him which are extant contain a strange admixture of history and legend. He is honoured both in the East and the West as a martyr, and the Greek acts of his martyrdom fix the date of his death as the persecution under Diocletian; but these acts are, by the confession even of Roman Catholic hagiologists, undoubtedly spurious. On the other hand, it is asserted (see Gibbon's *Decline and Fall*, ii. 323) that the canonisation of G. is one of the many errors which Protestant historians freely impute to the Roman calendar, and that the George who is thus reputed a saint and martyr is no other than the turbulent and unscrupulous Arian partisan, George of Cappadocia, whom his Arian followers revered as a saint, and imposed as such upon the credulity of their Catholic countrymen. It must be confessed, however, that the best modern authorities, Catholic and Protestant, agree in admitting the great improbability of this allegation. Heylin is of one mind in this matter with the Jesuit Papebroch, and Dean Milman adopts the arguments, and agrees in the

opinion of the Roman Catholic Bishop Milner. The truth is, that whatever is to be said of the early accounts of the martyrdom of G., the fact of his being honoured as a martyr by the Catholic church, of churches being dedicated to him, and of the Hellespont being called 'St George's Arm,' is traced by Papebroch, by Milner, and by other writers to so early a date, and brought so immediately into contact with the times of the angry conflicts in which George of Cappadocia figured as an Arian leader, that it would be just as reasonable to believe that the Catholics of England at the present day would accept Lord George Gordon as a Catholic saint, as to suppose that the Catholics of the East—while the tomb of Athanasius was hardly closed upon his honoured relics—would accept as a sainted martyr his cruel and unscrupulous persecutor. Indeed it cannot be doubted that the St G. of the Eastern Church is a real personage, and of an earlier date than George of Cappadocia—very probably of the date to which these acts, though otherwise false, assign him. The legend of his conflict with the Dragon arose most probably out of a symbolical or allegorical representation of his contest with the pagan persecutor. As in this ancient legend St G. appears as a soldier, he was early regarded as one of the patrons of the military profession. Under this title, he was honoured in France as early as the 6th c.; but it was not until after the Crusades, who ascribed their success at the siege of Antioch to his intercession, returned to Europe from the Holy War, that the religious honour paid to him reached its full development. He was selected as the patron saint of the Republic of Genoa and also of England. At the council of Oxford, in 1222, his feast was ordered to be kept as a national festival. In 1330, he was made the patron of the Order of the Garter by Edward III.; and even since the Reformation, the ancient sentiment is still popularly maintained.

GEORGE, St, BANNER OF, white with a red cross. According to Sir N. H. Nicolas, the cross of St George was worn as a badge over the armour by every English soldier 'in the 14th and subsequent centuries, even if the custom did not prevail at a much earlier period,' to indicate that he was in the service of the crown. On the invasion of Scotland by Richard II. in 1386, it was ordained 'That everi man of what estate, condicion, or nation they be of, so that he be of oure partie, bere a signe of the armes of Saint George, large, bothe before and behynde, upon parell that yf he be slayne or wounded to deth, he that hath so doon to hym shall not be putte to deth for defaulte of the crosse that he lacketh. And that non enemy do bere the same token or crosse of St George, notwithstanding if he be prisoner, upon payne of deth.' A similar ordinance was adopted by Henry V. for the government of his army in France.

GEORGE, THE, the badge of the Order of the Garter (q. v.), exhibiting the figure of St George on horseback piercing the falling dragon, which lies on a mount.

GEORGE'S CHANNEL, St, is the name applied to the south portion of that arm of the Atlantic which separates Ireland from the United Kingdom. A line, extending from Holyhead in Wales to Dublin, would form the northern limit of this channel; and a similar line from St David's Head to Wexford, would form its southern limit. At its northern extremity it is 64 miles in width, and at its southern it is about 62 miles wide; its length, from north-east to south-west, is about 100 miles.

GEORGETOWN, a city and port of entry of North America, in the state of Maryland, is situated

GEORGETOWN—GEORGIA.

on a range of hills, the highest of which are denominated the *Heights*, on the left bank of the Potomac, two miles north-west of Washington (q. v.). From the Heights, which are occupied by elegant villas, a magnificent view of the cities of G., Washington, and of the surrounding country is obtained. G. is quiet and antiquated, and has a reputation for its literary advantages and for its refined society. Its principal institutions are the Georgetown College, under the management of the Jesuits, and the convent of Visitation Nuns—attached to which is an academy for females with about 100 pupils. Here the Alexandria branch of the Chesapeake and Ohio Canal is carried across the Potomac by means of an enormous viaduct 1446 feet long, and 36 feet above the ordinary level of the water. As it is the only port in the district of Columbia, and situated at the head of the navigation of the Potomac, 125 miles from its mouth, its foreign commerce and coasting trade are important. It keeps 50 mills in operation to supply its trade in flour. It is one of the greatest markets in the United States for shad and herrings, of which vast quantities are caught in the Potomac, and brought here for barrelling. Pop. 1850, 8336; 1854, 10,000.

GEORGETOWN (Dutch, *Stabroek*), the capital of British Guiana, is situated at the mouth, and on the right or eastern shore, of the river Demerara, in lat. 6° 49' 20" N., and long. 58° 11' 30" W. It is handsomely built, and consists of spacious, clean streets, intersecting at right angles, and composed of neat wooden houses, which are raised three or four feet above the ground, in order to avoid the damp, have open verandahs in front, and are embosomed in trees, of which the cabbage-palm, the cocoa-nut, and the orange tree are the chief. Most of the streets are traversed by canals, communicating with each other and with the river. Of the public buildings, the town-hall, an elegant structure, with marble-paved galleries resting on cast-iron columns, the Episcopal cathedral, and the Colonial Hospital, are the principal. There are also a mariners' hospital, numerous churches and schools, astronomical and botanical societies, barracks, theatres, and a market-place surrounded by elegant and well-stocked shops. G., owing to the low and swampy character of the district in which it stands, is unhealthy. Yellow and intermittent fevers, diarrhoea, dysentery, and dropsey are local diseases. The chief exports of G. are sugar, coffee, and rum; and in 1853 its trade employed 591 vessels of 101,764 tons. Pop. 1851, 25,508, of which about 20,000 were negroes and people of colour.

GEORGIA, *GULF OF*, an arm of the North Pacific Ocean, between Vancouver's Island and the mainland of British Columbia. It averages 20 miles in width, is 100 miles in length, receives Fraser River (q. v.), and communicates with the open ocean by Queen Charlotte's Sound in the north, and by the Strait of Fuca in the south. Its southerly entrance is about lat. 49° N. and long. 124° W.

GEORGIA, an Atlantic state of the American Union, and one of the 13 original states, extends in lat. from 30° 21' to 35° N., and in long. from 80° 48' to 85° 40' W. It is bounded on the N. and N.E. by the states of Tennessee, North Carolina, and South Carolina, on the W. by Alabama, and on the S. by Florida. Its extreme length, from north to south, is 320 miles; and its greatest breadth, from east to west, is 254 miles. Its area is 58,000 square miles; and its population in 1860 was 1,082,797. The population in 1859 was 1,014,418, of which the whites numbered 571,534; the slaves, 439,592; and the free-coloured, 3292. In 1859, the state of

G. had a representative population of 778,054, and was entitled to 8 members in the national house of representatives, and to 10 electoral votes for president of the United States. G. presents every variety of surface, rising from low alluvial lands and swamps along the shore through an undulating and rough hilly country to the Blue Ridge Mountains, in the north and north-west of the state. The chief rivers are the Savannah, which forms the north-east boundary of the state, and the Chattahoochee, which forms a great portion of its south-west boundary. The course of all the important rivers is toward the south and south-east. Only about a fifth of the entire area of the state is under cultivation; but owing to the diversity of climate and soil, the productions are wonderful in their variety. The islands that fringe the coast are fertile in cotton of a superior quality: the bottom lands of the great rivers produce rice, cotton, Indian corn, and sugar; further west are the 'pine barrens,' valuable for their timber, and easily cultivable; the central region consists of a loamy soil, once productive, but now impoverished; and the north, the Cherokee country, contains lands which, although long worked by the Indians, still produce from 50 to 76 bushels of grain to the acre. Gold, though not now sought for, was once found here in some quantity; silver, copper, iron, lead, marble, and precious stones also occur. In 1858, G. had upwards of twenty lines of railway, whose total length reached to more than 1200 miles. The public debt of G.—to be paid in instalments at stated periods—amounted in October 1860 to 3,170,750 dollars, the interest of which was 164,775 dollars a year. The balance in the treasury, October 1860, after the payment of all expenses, amounted to 274,820 dollars. The value of the exports in 1857 was 10,857,634 dollars; and of the imports in the same year, 779,909 dollars. G. is divided into 112 states; capital, Milledgeville. G. was the latest colonised of the original states, the first settlers landing at Charleston in January 1733.

GEORGIA, the name formerly applied in a general manner to the region now called Russian Transcaucasia (see TRANSCAUCASIA), which forms the isthmus connecting Europe with Turkey-in-Asia, and is bounded by the Caucasian mountains on the north, and by the Armenian mountains on the south. The Persian name is *Gurjestan*; the Russian, *Grusia*; and the native, *Iberia*; the name of G. arose either from the numerous kings called George that ruled over the country, or from the patron saint being St George.

The early history of the Georgians, who trace their origin to Thargamos, a great-grandson of Japhet, is wrapped in fable. Mtakhetoa, who is said to have built Mtaketha, the ancient capital of the country, the ruins of which are still visible near Tiflis, plays a prominent part in it. They appear, however, in authentic history in the time of Alexander the Great to whom they submitted. After the death of Alexander, in the year 324 B. C., they were delivered from a foreign yoke by Pharnawas, and united in one kingdom. With Pharnawas begins the series of the Mephé or kings of G., who, under a variety of dynasties, ruled the country almost without interruption for more than 2000 years. By the end of the 4th c., Christianity had diffused itself throughout the country, and through it G. became connected with the Eastern empire, with which it joined in repelling the attacks of the Sassanides. After the empire of the Sassanides had been destroyed by the Arabs, the latter carried their conquests into G., which now became a province of the Arabian Califate. Toward the end of the

GEORGIA BARK—GERACE.

9th c., during the decline of the Arabian Caliphate, the Georgians recovered their independence for a short period, but it was only to become tributary in the 10th c. to those dynasties which, in Persia, took the place of the Califs. Toward the end of the 10th c., they again achieved independence, and inaugurated the most brilliant era in Georgian history; for from this period to the 13th c., when they were conquered by the Mongols, G. was governed by a series of able sovereigns, who increased its extent, repulsed its enemies, and raised it to great prosperity. Toward the end of the 14th c. the country fell into the hands of Timour, who, however, was driven from it in the beginning of the following century by George VII. Alexander I., the successor of George VII., committed the fatal error of dividing the kingdom between his three sons. Each of these states was again divided, and at one time 26 different princes reigned in Georgia. The general history of G. now divides into two parts: that of the eastern states, Karthli and Kacheth; and that of the western states, including Imereth, Mingrelia, and Guria. From the 16th to the 18th c., the eastern states had been heavily oppressed by Persia, and in 1799 Gregory XI., after many attempts to establish their independence, resigned the states in favour of Paul Emperor of Russia, and in 1802 the Emperor Alexander proclaimed the territory a Russian province. Of the three states forming Western G., Guria fell into the hands of Russia in 1801, and formally surrendered itself to that empire by the treaty of 1810; Mingrelia was virtually added to Russia in 1803; and the state of Imereth toward the close of the 18th century. Thus the whole of G. has been brought under the dominion of Russia, and has been united, along with the other Transcaucasian possessions of that country, into a general government, the head of which unites in his own person the military and civil powers, and exercises military supremacy over the whole of the Caucasus. For the character of the country of G., and for its capabilities, see TRANSCAUCASIA.

The Georgians are one of that numerous group of nations or tribes that inhabit the Caucasus, to which Dr Latham has given the name of Dioscurians (see CAUCASUS). They are celebrated for their beauty, and under the Mohammedan rule, the white slaves of Western Asia and of Egypt were mostly drawn from among them and the Circassians. Though endowed by nature with mental no less than physical advantages, the long course of oppression to which they have been subjected has had its effect both upon their intelligence and their morality. Despite the long supremacy and cruel tyranny of their Mohammedan conquerors, they have, as a nation, remained faithful to the Christian religion, according to the doctrines of the Greek church. In Guria, however, nearly half the inhabitants have gone over to the religion of Islam. The condition of the people, although somewhat ameliorated under Russian rule, is on the whole deplorable.

The language of the Georgians is harsh, but regular and forcible. It has a peculiar structure, and Dr Latham considers it as having nearer affinities with the Tibetan and other monosyllabic tongues, than with the Aryan. The literature, which is not altogether unimportant, begins with the introduction of Christianity into the country, and consists chiefly of ecclesiastical writings, translations of the Bible, the fathers, Plato, Aristotle, and their commentators. Profane literature flourished chiefly in the 17th c., and consists mainly of poetry and chronicles, particularly of an ecclesiastical character. A few heroic poems may be traced

back to the time of Queen Tamar (1184—1206). Scientific works are few in number, and with the exception of a few historical works, are of no importance. Recently, however, a greater zeal in the cultivation of the sciences has begun to shew itself among the Georgians, and under the Russian government the system of education and instruction has progressed considerably. On the other hand, it must be regarded as a circumstance unfavourable to the mental culture of the country, that, in 1807, the archives and scientific works of G. were conveyed to St Petersburg. The person most thoroughly conversant with the language, literature, and history of G. is Brosset. Besides the translation of a Georgian chronicle, he has published, among other works, the *Elements de la Langue Georgienne* (Paris, 1837), the *Rapport sur un Voyage Archéologique dans la Georgie et dans l'Arménie, exécuté en 1847—1848* (Petersburg, 1850—1851), *L'Histoire de la Georgie*, in Georgian and French, and *Additions et Eclaircissements à l'Histoire de la Georgie* (Petersburg, 1851).

GEORGIA BARK. See PINCKNEYA.

GEORGSWALDE, a small town on the northern border of Bohemia, 64 miles north of Prague. It has a mineral spring and some manufactures of linen. Pop. 5100.

GEOTEUTHIS, a genus of fossil calamaries, peculiar to the Oolitic period. The shell or horny pen is broad and truncated in front, and pointed behind, with the lateral wings shorter than the shaft. Some specimens from the Oxford clay are remarkably preserved, still shewing the muscular mouth, the bases of the arms, and the ink-bag. The ink has been made into Sepia. Some of the ink-bags from the Lias are nearly a foot long, and are invested with a brilliant nacreous layer. Upwards of a dozen species have been found.

GERA, a town of Germany, the chief place in the small principality of Reuss, is pleasantly situated on the right bank of the White Elster, 35 miles south-south-west of Leipzig. It is handsomely built, with broad and regular streets, and has six squares, a castle, a fine town hall, and several religious and educational institutions. There are extensive manufactures of woollen and cotton goods, also machine making, and manufactures of soap, gloves, leather, hats, tobacco, waxcloth, ironware, stoneware, and porcelain. In 1850, 4925 looms were employed here in the production of woollen goods, which are exported to various parts of the world to the value of about £450,000 annually. Pop. 12,000.

GERACE, an ancient commercial town in the south of Italy, chief town of the district of the same name, in the province of Calabria Ultra I., occupies a beautiful and fertile situation on the upper slopes of the Apennines, at about four miles distance from the Ionian Sea. On the destruction of the ancient town of Locri by the Saracens in the 12th c., the inhabitants, out of the ruins of their homes, constructed a new settlement about four miles from the site of Locri, on the sea-shore, and called it Santa Ciriaque, which has since become Gerace. This town has suffered severely from repeated earthquakes, in one of which, in 1783, both the cathedral and the citadel, a fortress of great strength, were reduced to ruins. In a neighbouring plain are seen ruins supposed to occupy the site of Locri Epizephyrii, an important city of Magna Grecia, celebrated by Pindar in more than one of his odes. Coins bearing the epigraph of Locri have been found in the vicinity of the ruins, and together with the Greek character borne by the ruined edifices, seem to support

this supposition. The modern G. is well-built, and owes its commercial prosperity to its silk factories and its trade in wine, a sweet white kind of which, known as 'Il Greco di Gerace,' is deservedly held in high repute. Pop. 5900.

GERANIUM, a genus of exogenous plants, the type of the natural order *Geraniaceae*, the limits of which correspond with those of the Linnean genus.

a, Geranium; b, Pelargonium;
c, Herb Robert (*Geranium Robertianum*).

This order contains at least 500 known species, very unequally distributed over the world, and particularly abounding at the Cape of Good Hope, of which country most of the species of the large genus *Pelargonium* are natives—a genus distinguished by an irregular corolla and by a nectariferous tube running down the flower-stalk. Many species of *Pelargonium*, and many fine hybrids and varieties produced by cultivation, are to be seen in green-houses, and some of them are frequent in cottage-windows. The name geranium is still very frequently given to them. The British *Geraniaceae* are thirteen species of *Geranium* and three of *Erodium*, all herbaceous. Some of them are common weeds in fields and gardens, with small flowers; others have large and beautiful flowers, and are among the finest ornaments of groves and meadows. Some species of *Geranium* are often cultivated in flower-gardens. The name *Geranium* (Gr. *geranos*, a crane), the popular English name *Crane's-bill*, and the German *Storchschnabel*, all refer to the beaked fruit. The *Geraniaceae* are generally characterised by astringency; many have a disagreeable, others a pleasantly aromatic and resinous smell, some a delightful fragrance. The STINKING CRANE'S-BILL or HERB ROBERT (*Geranium Robertianum*), a common weed in Britain, with a diffuse habit, deeply divided leaves, and small flowers, has been used medicinally as an astringent, and in nephritic complaints. *G. maculatum*, a North American species, with flowers of considerable beauty, is the most valuable medicinal plant of the order. Its root, called ALUM ROOT in America, is extremely astringent, and abounds in tannin: it is used for gargles and as a medicine in various diseases.

A few *Geraniaceae* produce edible tubers: those of *Geranium tuberosum* are eaten in the south of Europe; those of *G. parviflorum* in Van Diemen's Land, where they are known as *Native Carrot*; and those of *Pelargonium triste* at the Cape of Good Hope. The leaves of *Pelargonium acetosum* and *P. peltatum* are edible, and gratefully acid. The cultivated *Geraniaceae* are propagated by seed or by cuttings; the shrubby kinds are very easily propa-

gated by cuttings. They require a light rich soil: a mixture of leaf mould and sand is very suitable. They are kept low by pruning, to increase their beauty and make them more productive of flowers.

GÉRARD, ETIENNE-AUGUSTE, COMTE, Marshal of France, was born at Damvilliers, in Lorraine, on the 4th of April 1773. He enrolled as a volunteer in the second battalion of the Meuse, and served during the campaign of 1792—1793 under Dumouriez and Jourdan, and afterwards accompanied Bernadotte on his embassy to Vienna, where he was the means of saving his master's life in the mêlée that ensued on his arrival. After rising rapidly through the different grades of promotion, he was appointed colonel on the 15th November 1800, and in 1805 aid-de-camp to his friend Bernadotte. He specially distinguished himself at Austerlitz (1805), in consequence of which he was appointed general of brigade, at Halle (1806), Jena (1806), Erfurt (1806), Lintz (1809), and Wagram (1809). On the morning after this last battle, he received the title of Baron of the Empire. He took part both in the wars of the Spanish Peninsula and in the Russian campaign; and in 1812 was made a general of division. Subsequently, Napoleon named him Count of the Empire. After the first restoration, he was named Grand Cross of the Legion of Honour, and Chevalier of St Louis, and received various honourable appointments. On the return of Napoleon from Elba, G. joined him, and commanded the fourth corps, numbering 16,000 men. At the battle of Ligny, G. was opposite to the centre of the Prussian position, which covered Ligny, and was thus in the hottest of the fight. On the morning of the 18th of June, G. was near Wavres, when firing was heard in the direction of Soignies, upon which a council was called, and if G.'s advice had been taken, the battle of Waterloo might perhaps have had a different result. After the second restoration, G. was obliged to leave France, and did not return till 1817. He was elected a member of the Chamber of Deputies in 1822; he also took an active part in the revolution of 1830, and commanded the troops appointed to maintain order and tranquillity in Paris. In 1831, Louis Philippe appointed G. a marshal of France, and gave him the command of the expedition to Belgium, in the course of which he distinguished himself by taking Antwerp in December 1832. In 1835 he succeeded Marshal Mortier as Grand Chancellor of the Legion of Honour. He died 17th of April 1855.

GÉRARD, FRANÇOIS PASCAL, BARON, one of the first historical and portrait painters of the modern French school, was born at Rome, 11th March 1770. At an early age, he went to France, and was apprenticed to Pajou, the sculptor, in Paris. He afterwards worked for some time in the studio of the painter Brenet, and in his 16th year became the pupil of David, but his artistic career was interrupted for several years by the Revolution. In 1795, he exhibited his first picture, 'Belisarius;' some time after, he painted 'Psyche receiving the First Kiss from Cupid.' Encouraged by his success, he now turned his attention to portrait-painting. Having gained Napoleon's favour, he was loaded with honours, and received, among other commissions, that of painting the Battle of Austerlitz, perhaps the most successful of his paintings illustrating the campaigns of Napoleon. But his grandest work—both as regards size and merit—is his 'Entrance of Henri Quatre into Paris.' It is 30 feet wide by 15 high, glowing with life, bright with colour, and accurate in costume. It was painted in 1817. G. was shortly after appointed first court-painter,

GERASA—GERHARDT'S NOTATION.

and raised to the rank of Baron by Louis XVIII. He died at Paris, 11th January 1837. G.'s most celebrated portraits are those of Napoleon in his Coronation Robes, the Queen of Naples and her Children, Talleyrand, Talma, Louis Philippe, and Madame Récamier. Of his other pictures, the best known are 'Ossian's Dream' (engraved by Godefroy), 'Homer' (engraved by Massard), 'Daphnis and Chloë,' 'Philip V.,' 'Corinna on the Promontory of Misena,' 'St Theresa Kneeling at the Altar,' and 'Thetis Bearing the Armour of Achilles.'

GERASA, in the time of the Romans, was a city of Palestine, on the eastern borders of Persæa. It was situated among the mountains of Gilead, about 20 miles east of the Jordan, and 25 north of Rabbath-Ammon, and attained a high degree of prosperity under the Antonines (138—180 A.D.). On the rise of Christianity, it became the seat of a bishopric, but subsequently sunk into decay. G. is now deserving of notice solely on account of its ruins, which are said to be the most beautiful and extensive in that part of Palestine lying east of the Jordan. In fact, it presents the appearance of a city in ruins, but which still preserves its original outlines. Great portions of the wall surrounding the town are in good preservation; three of the gateways are almost perfect, and within the city more than 230 columns are still standing on their pedestals.

GERBI, GERBA, or JERBA (the Meninx of Strabo and Pliny), a small island on the north coast of Africa belonging to the state of Tunis, is situated in the Gulf of Cabea, and is separated by a strait from a headland on the shore. It is about 20 miles long and 12 miles broad, and is fertile and populous. Shawls of brilliant colours, beautiful silk and woollen fabrics of the finest texture, bournous and blankets, are manufactured. This island contains a triumphal arch in honour of Antoninus and Verus, and a pyramid from 25 to 30 feet in height, built up of the skulls of the Spanish soldiers who fell here in a disastrous battle with the Turks in the 6th century.

GERHARDT, KARL FRIEDRICH, an eminent chemist, was born at Strasburg on the 21st of August 1816, and died in that city on the 19th of August 1856. At the age of fifteen, he was sent to the Polytechnic School of Carlsruhe, where his attendance at Professor Walchner's lectures first awakened in his mind a taste for chemistry. After two years' residence in this town he removed to Leipzig, where he attended the lectures of Erdmann, which seem to have developed in him an irresistible passion for questions of speculative chemistry.

On his return home, he reluctantly entered upon the business of his father, who was a manufacturer of chemical products; but the requirements of commerce seem to have been intensely repugnant to him, and in a hasty moment of passion he enlisted (being now in his twentieth year) in a regiment of chasseurs. He soon, however, found a military life as insupportable as a commercial career, and in the course of three months he purchased his discharge, and at once set out for the laboratory of Giessen, where he worked under Liebig's superintendence for eighteen months. In 1838 he arrived in Paris, where he was cordially welcomed by Dumas. Here he gave lectures and instructions in chemistry, and, with Chevreul's permission, worked in the laboratory of the Jardin des Plantes, where, in association with his friend Cahours (to whose memoir of G. we are indebted for many of the facts noticed in this article), he commenced his important researches on the essential oils. In 1844 he was appointed

professor of General Chemistry in the Faculty of Sciences at Montpellier, and in the same year he married the youngest daughter of the late Dr James Sanders of Edinburgh. About this time he published his *Précis de Chimie Organique*, in which he sketches the idea of 'Homologous and Heterologous Series' (q. v.), which at a later period he so successfully developed. In 1845, in association with Laurent, he commenced the *Comptes rendus des Travaux de Chimie publiés en France et à l'Étranger*, which were continued till 1848. In 1848, he resigned his chair and returned to Paris, in order to follow out uninterruptedly his special investigations; and in that city he established, between the years 1849 and 1855, in successive memoirs, his views of series (already adverted to) and the theory of types, with which his name will be ever associated in the history of chemistry. It was there, also, that he gave to the scientific world his remarkable researches upon the anhydrous acids and the oxides. All his ideas and his discoveries are embodied in his *Traité de Chimie Organique* (1853—1856, 4 vols.), which forms, to use the words of his friend and biographer Cahours, 'an important monument of modern science.' He had hardly completed the correction of the last proof of this great work, when, after an illness of only two days, he was surprised by the hand of death at the very period when he seemed to be beginning to enjoy the fruit of his labours; for he had just received the diploma of corresponding member of the Academy of Sciences at Paris, and in the previous year he was appointed professor of chemistry at Strasbourg.

GERHARDT'S NOTATION is now introduced, not only into numerous foreign works on chemistry, but into some of our recent English manuals—as, for example, Comington's *Handbook of Chemical Analyses*, Odling's *Manual of Chemistry*, &c.; and being employed by a large section of English chemists—as, for example, Professors Williamson, Brodie, Hofmann, and Odling—requires a brief notice. On certain theoretical grounds, Gerhardt has doubled the combining or equivalent numbers of oxygen, carbon, sulphur, selenia, and tellurium; the other numbers remaining unaltered. We give in the following table the ordinary and Gerhardt's numbers:

	Ordinary Equivalent.	Gerhardt's Equivalent.
O,	8	16
C,	6	12
S,	16	32
Se,	30.75	79.5
Te,	64.5	129.

The examination of a few formulæ will readily enable the reader to translate from one system into the other:

Compounds.	Ordinary Formula.	Gerhardt's Formula.
Water,	HO	H ₂ O
Potash,	KO	K ₂ O
Hydrate of Potash,	KO.HO	KHO
Hydrated Nitric Acid,	HO.NO	NO ₂ H
Hydrated Sulphuric Acid,	HO.SO	SO ₂ H ₂
Hydrated Acetic Acid,	HO.C ₂ H ₃ O	C ₂ H ₄ O ₂
Alcohol,	HO.C ₂ H ₅ O	C ₂ H ₆ O

In Gerhardt's formulæ we have printed in italics the symbols whose equivalents are changed. Each system of notation has its advantages, but upon the whole we are inclined to agree with Professor Miller, that 'the question to be considered is not simply, what is in the abstract the best mode of notation, but what, considering all the circumstances of the science, possesses the greatest advantage. That system of notation which is

consistent with itself, and which lends itself most completely to the expression of the various theories and aspects of the science which have been maintained, or may be maintained, is therefore, philosophically speaking, the best. And such grounds, it appears to me, exist for continuing to use the system hitherto adopted.'

GERIZIM AND EBAL, two mountains celebrated in Scripture story. They are separated from each other by a narrow valley about 200 yards wide, in which stands the town of Nābulus, the ancient Shechem or Sychar, the metropolis of the Samaritan sect. They are nearly equal in altitude, neither of them exceeding 700 or 800 feet above the level of the valley, which, however, is itself 1800 feet above the sea. The view from the top of Mount G., the southern hill, is said to be among the finest in Palestine, embracing, as it does, glimpses of the blue waters of the Mediterranean on the west, the snow-capped heights of Hermon on the north, and on the east the wall of the Trans-Jordanic mountains, broken by the deep cleft of the brook Jabbok.

In all probability, Mount G., and not the mere hillock called Moriah, on which Solomon afterwards built the Temple, was the place where Abraham offered up his son Isaac. Along with Mount Ebal, it was also the scene of a grand and impressive ceremony, in which the whole people of Israel took part after crossing the Jordan, in obedience to a command which Moses had given them. Half of the tribes stood upon the declivities of the one hill; the rest occupied the sides of the other, while in the valley between, the Levites, surrounding the sacred ark, pronounced, 'with loud voice,' the blessings affixed to the performance of the law, and the curses affixed to the neglect of it. According to the Mishna, their manner of procedure was as follows: They first turned towards Gerizim, and pronounced the blessing, whereupon the vast host that thronged the ascent of that hill rolled back their multitudinous 'Amen;' then turning towards Ebal, they uttered the corresponding malediction, to which the tribes there stationed responded in deep and solemn tones. In this way, alternating blessing and curse, they went through the whole series. The narrative of the ceremony (which is to be found in the 27th chapter of Deuteronomy) gives only the curses—the customary explanation of which fact is, that probably these were merely the reverse form of the blessings, and may have been selected by the writer of the book on account of the greater awe inspired, among a rude people, by a malediction than a benediction. At a later period the Samaritans, by permission of Alexander the Great, built a temple on Mount G., as a rival to that of Jerusalem, and organised a rival priesthood. And though this temple was destroyed by Hyrcanus about 200 years after, the mountain on which it stood continued to be held sacred by the Samaritans. It was to Mount G. that the 'woman of Samaria' referred when she said to her Saviour: 'Our fathers worshipped in *this* mountain, and ye say that in Jerusalem is the place where men ought to worship.' Subsequently, a Christian church in honour of the Virgin was built on it, which Justinian surrounded with a strong wall to protect it against the assaults of the Samaritans, who were even then a powerful and important sect. The ruins of this wall are still visible.

GERIKI, a considerable town of Africa, is situated in the Sūdān, in the district of Sokoto, in lat. 12° 28' N., and long. 9° 10' E. It is surrounded by a wall surmounted with pinnacles. Its inhabitants are notorious for their thievish propensities, and for

their aversion to agriculture, and, indeed, to any form of industry. Population estimated at 15,000.

GERLACHE, ETIENNE CONSTANTIN, BARON DE, a native of the province of Luxembourg, in Belgium, was born on the 26th December 1785. In 1824, he was elected as deputy from the province of Liege to the second chamber of the 'States General.' At the time of the Revolution, G. presided over the committee appointed to revise the constitution, and was head of the deputation sent to offer the crown to Prince Leopold of Saxe-Coburg. In 1831, he became president of congress, and in that capacity received the oath exacted from the king by the constitution, and the following year was appointed first president of the 'court of cassation.' In 1843, the king conferred on him the title of baron. Since his election as deputy in 1824, he has supported the Catholic party, and is now considered as one of their chief leaders. G. has also acquired a literary reputation. The most important of his works are the following: *Memoires sur les Changements à apporter aux Tarifs du Royaume*, which appeared between 1821 and 1824, and were addressed to the king; *Histoire du Royaume des Pays-Bas, depuis 1814 jusqu'en 1830* (Brussels, 1839), besides other works of local interest.

GERMAN, SAN, a town in the south-west of the Spanish island of Porto Rico, stands in lat. 18° 10' N., long. 67° W. It is situated about 10 miles from the sea, in the centre of a district productive in cotton, coffee, and cattle. Its population is estimated at 9125.

GERMAN BARM. See YEAST.

GERMAN CATHOLICS is the name generally given to a religious sect that has recently sprung up in Germany in the bosom of the Roman Catholic Church. Though retaining the designation Catholics—i. e., universal—they form independent congregations, and most commonly style themselves Christian Catholics. So far as their general principles are concerned, the G. C. stand upon Protestant ground; but neither in theory nor practice are they evangelical Protestants, nor do they wish to be accounted such.

Whatever might be the deeper causes of the schism, the immediate occasion of it was the exhibition of the Holy Coat at Treves. In 1844, Bishop Arnoldi appointed a special pilgrimage and service to this relic, to be preceded by confession and remission of sins. This proceeding called forth a protest from J. Ronge (pronounced Rongé, the *g* hard), a priest in Silesia, who, having quarrelled with the authorities of his church, had been suspended from his office, and was living in retirement. Ronge addressed a public letter to Bishop Arnoldi, October 1, 1844, in which he characterised the exhibition of the coat as idolatry. Ronge's voice found a vivid response in the minds of many Catholics, and was also approved by Protestants.

A short time previous to the publication of this letter, J. Czeraki, a priest at Schneidemühl, in Posen, had seceded from the Roman Catholic Church, and was about to form a congregation of 'Christian Apostolic Catholics.' Czeraki and Ronge were naturally drawn into confederacy. Ronge at last addressed an appeal to the lower orders of the priesthood, calling upon them to use their influence in the pulpit and everywhere to break the power of the court of Rome, and priestcraft in general, throughout Germany; to set up a national German Church independent of Rome, and governed by councils and synods; to abolish auricular confession, the Latin mass, and the celibacy of the priests; and to aim at liberty of conscience for all Christians.

and perfect freedom for the religious education of children.

The first congregation of the new church was formed at Schneidemühl, and took the name of Christian Catholic. The confession of faith, which was drawn up by Czerski, differed little in point of doctrine from that of the Catholic Church. The Holy Scriptures and the Nicene Creed were held to be the only standards of Christian faith, and were to be understood in the sense patent to every enlightened and pious Christian. Nothing was said against the worship of saints and relics, pilgrimages, confession, &c. This Confession of Schneidemühl served many other congregations as a groundwork, though some of them modified it in various ways, and expressed themselves more definitely. The new sect quickly increased. At the beginning of 1845, more than a hundred congregations were in existence. The congregation which was formed at Breslau is noticeable from the confession of faith which it issued, drawn up under the influence of Ronge, who had been chosen preacher. This confession completely departed from the doctrine and ritual of the Roman Catholic church. The Scripture was laid down to be the only rule of Christian faith, and no external authority, it was added, can be allowed to interfere with the free interpretation of it. The essentials of belief were restricted to a few doctrines: belief in God as the Creator and Governor of the world, and the Father of all men; in Christ as the Saviour, in the Holy Spirit, the holy Christian Church, the forgiveness of sins, and eternal life. Baptism and the Lord's Supper were held to be the only sacraments. Confirmation was retained, but most of the rites and practices peculiar to the Roman Catholic church were given up.

The need of something like concert being felt, the first council of German Catholics was held at Leipsic, March 22, 1845, and attended by deputies from many of the leading congregations, others signifying their willingness to abide by the decisions that might be come to. The principles of the Breslau Confession were mostly adopted. The interpretation of Scripture, the only source of Christian belief, was left to the free exercise of reason, pervaded and actuated by the 'Christian idea.' Forms of worship were to be adapted to the requirements of time and place. With regard to church government, the council declared in favour of the presbyterial and synodal constitution. The congregations were to have the free election of their clergy and eldership.

The effect of this union was to increase the number of congregations, which by the end of 1845 amounted to about 300. Numbers of leading Catholics, professors and others, joined the movement; and learned Protestants, like Gervinus, looked upon it as a momentous event in the history of Germany. Individual Protestant clergymen went over to the body; and all those Protestants who, from dissatisfaction with the state church, had formed what are called 'free' or independent congregations, entered more or less into relations with it. The local boards and magistracy also shewed great favour to the cause, and often supported it by granting the use of Protestant churches, and even funds.

But German Catholicism was destined soon to find enemies both within and without. To say nothing of orthodox Catholics, conservative Protestantism began to suspect it as an undermining of religion in general, and dangerous to the welfare of 'church and state.' And as the movement fell in with the liberal tendencies of the times in general, the governments took the alarm, and set themselves to check its spread. Saxony took the lead, and Prussia soon followed, in imposing vexatious, and even

tyrannical restrictions upon the 'Dissidents,' as they were styled by the authorities. In Baden, they were even denied the rights of burghers, while Austria, pre-eminent in religious bigotry, sent them out of her territories.

It was more, however, internal disagreements than state persecutions that checked the prosperity of German Catholicism, as was to be anticipated from the wide discrepancy between the views of Czerski and those of Ronge. Czerski and his adherents held closely by the doctrines and ritual of Rome, and issued successive confessions, laying down more and more definitely the essential points of belief, such as the divinity of Christ, and other positive doctrines. Ronge's party, on the other hand, approached nearer and nearer to the Rationalists, and, leaving the province of religion altogether, occupied themselves with free-thinking theories and democratical politics. This led to numerous disagreements between congregations and clergymen, and discouraged the spread of the movement. When the second council was held in Berlin in 1847, the interest had greatly declined.

When the great storm of 1848 burst, the German Catholics, as well as other bodies, had free space for their exertions, which, however, took mostly a political direction. Some additions were made to the number of the congregations, especially in Austria. Ronge was active in travelling and preaching, and although his freethinking and political tendencies were repudiated by numbers of the body, they predominated in many places, and found expression in a series of publications, among others, in Rau's *Catechism of the Christian Religion of Reason*, and Shell's *Book of Religion*. After the political reaction set in, strong measures were taken against the German Catholics. The early enthusiasm of the movement apparently died out, and after the dissolution of the Frankfurt parliament, Ronge retired to London, where he has since resided. The individual congregations once formed still continue to exist, though in a depressed condition, except in Austria, where they have been altogether suppressed. A conference was held at Köthen in 1850, at which it was proposed to form an alliance with the Free congregations formed of dissenters from the Protestant church, and a diet was fixed for 1852, but it did not meet. Since then, German Catholicism has been rapidly diminishing all over Germany, and at the Gotha conference of 1858 there were only 42 representatives present. Compare Kampe's *Geschichte der Religiösen Bewegungen der Neueren Zeit* (Leip. 1856).

GERMAN, COUSIN. Cousins-german, or first cousins, are those who are related to each other by their fathers and mothers having been sisters or brothers, or the father or mother of the one being the sister or brother of the other. The term has no relation to German, in the sense of Teutonic, but comes from the Latin word *germanus*, which again is derived from *germen*, a young bud or branch. Consins-german are, therefore, those who are the buds or branches of the same tree, and they have in reality always one grandfather in common.

GERMAN OCEAN. See NORTH SEA.

GERMAN PASTE, used for feeding birds such as larks, thrushes, nightingales, and other singing-birds, especially those which in their wild state feed chiefly upon insects. Take 2 lbs. pea-meal, $\frac{1}{2}$ lb. of sweet almonds blanched, $\frac{1}{2}$ lb. of fresh butter or lard, 5 oz. moist sugar, $\frac{1}{2}$ dr. of hay saffron, and 3 eggs boiled hard. Beat them into a smooth paste, using sufficient water to give it the consistence required for granulating by passing it through a colander; then expose the granulated

paste to the air in a warm place until it is quite hard and dry. If properly prepared and dried, it will keep good in a dry place for a year or more.

GERMAN PHILOSOPHY. When we speak of the philosophy of Germany, we do not necessarily imply that it differs from the philosophy of any other country in respect of the problems it seeks to solve, any more than when we compare the German chemistry with that of France or England. To characterise German philosophy, means nothing more than to point out the peculiar path that German thinkers have followed, and the degree of success that has attended their investigations, in seeking to answer those speculative questions which are understood to form the domain of philosophy, and which concern all men, if they concern any. Understood in this sense, German philosophy claims a high place—according to many, the highest. At least, for almost a century now, a more general interest has been taken in the cultivation of philosophy in Germany than elsewhere, and abstruse and deep speculation has been chiefly represented by German thinkers. That country has thus made up for the ground she lost by continuing to adhere to the traditional forms of scholastic philosophy after they had been forsaken in France and England. This spread of philosophic culture was coincident with the perfecting and adaptation of the German language to prose composition. For though Leibnitz confined himself in his philosophical writings to the Latin and French languages, Chr. Thomasius, about the same time, had begun to employ the mother-tongue both in academic lecturing and in writing, a practice which was extended by the numerous writings of Chr. Wolf. The expansion of German literature in the last half of the 18th c. completely emancipated speculation from the trammels of a foreign idiom, and alongside of a rich poetical literature there sprang up a philosophy which may claim comparison with that of Greece.

As regards the scientific characteristics of German philosophy, it may be remarked that the systems put forth by Bacon in England, Descartes in France, and Spinoza in Holland, had but little influence in Germany at the time of their appearance. It was Locke that first awakened any considerable attention. The empiricism of this philosopher, who grounds all knowledge on experience, and makes psychology the regulator of metaphysic, called forth the opposition of Leibnitz, the first German that made an epoch in the history of modern philosophy, and who, from the varied impulse he communicated, must be looked upon as the creator of the philosophic spirit in Germany. At the same time the fundamental doctrines of Leibnitz's system—that of monads, of a pre-established harmony, and of innate ideas—were rather genial hypotheses than regularly established propositions. To remedy this, Wolf endeavoured to construct a system of philosophy complete in all its parts as required by the forms of logic, in doing which, however, he set aside precisely those doctrines that formed the characteristics of Leibnitz's philosophy. The great influence exercised by Wolf is shewn by the wide circulation of his writings, and the multitude of his disciples and adherents. Wolf himself, however, outlived his fame, and the original philosophic mind in Germany went to sleep for a period, during which a sort of Eclecticism, without any fundamental principle—the so-called philosophy of 'common sense,' prevalent in England and France in the 18th c.—became generally spread. This period, however, was not without great intellectual excitement of other kinds. Poetry, reform in education, politics, and religious enlightenment, keenly occupied men's minds; old customs and associations, both in family and political life,

were shaken; and preparation was silently going on for a great and radical revolution.

Kant, with whom the next period of German philosophy begins, thus found an age ready to receive impressions; and, although the *Kritik der Reinen Vernunft* (Critique of the Pure Reason) was at first in danger of being overlooked, when a hearing was once obtained, that and his other critical works, which, after long preparation, appeared in rapid succession, communicated a profound impulse to the scientific world. This arose not more from the novelty and the comprehensiveness of his researches, than from the circumstance that their aim fell in with the tendencies of the age. The exclusion of everything dictated by caprice or sentiment, the maintenance of the independence of speculative inquiry, the reference of all theoretical speculation to the field of experience accessible to it, and the elevation of the moral element to the highest and ultimate object of all human endeavour, form the leading traits of his philosophy, which he recommended to consideration, more from its importance to man and society than to philosophers. He also entertained the hope that, through the critical inquiry into the nature of the human mind, it might be possible to reconcile empiricism and rationalism, sensualism and spiritualism, and other philosophical opposites, and discover a series of comprehensive principles to which all philosophical disputes might be referred in the last resort. This hope was disappointed; among other causes, because Kant sought to ground the old metaphysic of the schools on a psychology which itself rested on the basis of that metaphysic. Besides, there was wanting in the heyday of Kantism any satisfactory point of unity for the several parts of philosophy. K. L. Reinhold was the first to point out this defect; and scepticism, as in C. Schulze's *Enchiridion*, and dogmatism in the writings of Eberhard and others, carried on a war with the 'critical' philosophy, but not, it must be confessed, with any great success. It was Fichte who found, or thought he had found, in the fact of consciousness, that absolute point of unity which Kant's 'Critique' had always pointed to. Fichte, following out the path on which Kant had entered, changed the half-idealism of Kant into a complete idealism, by declaring the Ego to be, not only the bearer and source of knowledge, but the only reality, the world being merely the ideas and active manifestations of the Ego. In the ego, being and knowing were identical, it was at once existence and knowledge, and nature appeared only as the reflex of its absolute activity.

With this idealism began a kind of revolutionary excitement in the philosophising minds of Germans, which contrasted strongly with the calm and sober spirit of Kant. System followed system; philosophical books appeared in shoals; and for a quarter of a century and more the interest was shared by the public in general. But the meteors that appeared in the philosophical sky of Germany vanished for the most part as suddenly as they had blazed forth. Schelling was the first that attained a general influence. F. H. Jacobi had previously recalled attention to Spinoza, and Schelling, influenced by the speculations of Spinoza, converted the idealism of Fichte into what is called 'the philosophy of identity.' This system set out originally with the assertion, that as Fichte educes nature out of the ego, so by an inverse process the ego may be educes out of nature; but that both these forms of philosophising have their ground in the *absolute* as the *identity* of all opposites—of the real and the ideal, of subject and object, of mind and matter. In carrying out this assertion, Schelling fixed upon intellectual intuition as the

kind of cognition alone corresponding to the absolute, or rather as identical with and representing the absolute. The organ of this intuition was called reason, and, as such, was opposed to the reflection of the understanding, which was held to be quite incapable of taking cognition of the absolute. The relation of the phenomenal world to the absolute was held to consist in this, that the absolute represents itself in the multiplicity of appearances, steps out of the state of 'indifference' into that of 'difference,' manifests itself in 'difference,' &c. Taking special cases, particularly in natural philosophy, Schelling endeavoured to demonstrate the existence of this identity in the midst of non-identity, and of non-identity in the midst of identity. In this attempt, however, neither Schelling nor his disciples effected much. For in undervaluing and neglecting experience and reflection, the door was opened to a fanciful mode of speculation, which in most cases had little more in common with science than the name; so that in the departments of poetry, religion, and social life, the Schelling philosophy often degenerated unto a blind groping, leading to the strangest aberrations of romanticism, mysticism, and tendency to Catholicism.

The philosophy of Hegel (q. v.) took the same general direction as that of Fichte and Schelling. Hegel attempted to develop, in regular organisation, the contents of the intellectual intuition (in plain words, the cognitions and ideas of the mind) by the dialectic or logical method. Though he broke loose from the prevalent fashion of indulging in an unbridled play of fanciful combinations, he did not content himself with the rules of logic recognised for thousands of years, but sought an expression for speculative thought in a dialectic of his own. The essence of this transcendental logic consisted in the analysis of all the established general conceptions; and the process or method consists in making each conception of itself generate its opposite, and, combining with this opposite, thus become enriched and enabled to advance to still higher stages. This method Hegel, with enduring perseverance, endeavoured to carry out through the whole field of philosophy; and divided his system into the three provinces of logic, philosophy of nature, and philosophy of mind.

While the systems above considered form pretty much a continuous line of progress, that of J. F. Herbart (q. v.), on the contrary, arose in opposition to the idealism of Fichte, and took a direction in complete antagonism to the dominant secular philosophy; and when we have named Herbart, along with Schelling and Hegel, we have named the only men that, since the era of Kant and Fichte, can lay claim to extended and general influence. For the well-nigh innumerable productions of other thinkers in this department, though often of individual merit, are only of secondary importance for the development of philosophy as a whole. None of them opened up any new leading path; they are occupied chiefly in defending or remodelling older systems, and applying them to particular departments of science, or in controversy with the dominant philosophy of the day. To this category belong the Kantian systems of Fichte and others; the physical speculations of Steffens, Oken, Schubert, &c.; the various attempts to lead back philosophy to empirical psychology; the peculiar speculative attempts of Schleiermacher, J. J. Wagner, Fichte the younger, A. Trendelenburg, &c.; the different tendencies within the Hegelian school; and lastly, the position which Schelling latterly took up with regard to his own earlier doctrines, and to the development given to them by others.

While philosophy during the last half century

was thus actively prosecuted as a science, a corresponding interest was taken in its history; in fact, it was Germans who first sought to grapple with the history of philosophy as a whole, and to throw light upon the principal departments of it by valuable special treatises. See PHILOSOPHY. The rapid succession of systems one after another, and the extravagances into which some of them ran, have, it is true, produced a lull in the interest taken in speculation; and to the former enthusiasm there has succeeded a sceptical aversion to all speculative inquiry. Still the influence that philosophy has had in elevating and strengthening the scientific mind of Germany, has been powerful and beneficial; and there are few departments of research in which the fruits of the philosophic spirit may not be seen in a deeper and more thorough mode of treatment.

GERMAN SILVER, the name given to an alloy formed of copper, zinc, and nickel. It is variable in its composition according to the requirements of the manufacturer, but may be stated for general purposes to consist of copper 60·0, zinc 30·0, nickel 20·0; this composition is very malleable, susceptible of high polish, and nearly as white as silver. This is used to imitate silver in articles which are rolled and stamped, and consequently require considerable malleability. By taking 55 parts of copper, 24·4 of zinc, and 20·6 of nickel, we obtain a very beautiful alloy, scarcely inferior in beauty to silver itself. For wire-drawing and very thin rolling, a tougher alloy is formed of copper, 60 parts; zinc, 25 parts; nickel, 20 parts; and for castings the following proportions are used—copper, 60 parts; zinc and copper, each 20 parts. Many other formulæ are in use arising from difference of opinion amongst the manufacturers as to the best proportions for their respective operations, usually, however, the aim is to obtain a silvery whiteness, and the largest proportion of malleability.

This alloy must not be confounded with other white alloys, such as Albata, Britannia metal, and nickel silver, which are used as substitutes for the true German silver. The first of these is composed of copper, zinc, nickel, and a little lead; the second of copper, zinc, tin, antimony, and sometimes bismuth; and the third of copper 60·0, nickel 22·2, zinc 17·8. This last differs only in its proportions from the German silver; it has the colour of highly polished silver, and is very hard. The colour of German silver being so near that of the precious metal, it is particularly well adapted for plating either by the old process of rolling with silver, or in the newer and now generally used process of electro-plating; the advantages are that a thinner deposit of silver can be used, and the articles made are not liable to the objection of the old process of plating on copper, which as soon as the silver began to wear off was rendered apparent by its red colour.

As alloys of the nature of German silver are easily oxidised when brought in contact with free acids (as, for example, with the acetic acid contained in vinegar), and as the salts of lead, copper, and nickel, that are thus formed are poisonous, it is not expedient to use spoons, dishes, &c., composed of German silver.

The extent to which it is now used is very great indeed, and, combined with electro-depositing, it has been the means of adding immensely to the national industry, the manufacturers of Birmingham and Sheffield supplying every quarter of the globe with a profusion of articles of taste and utility in electro-plate in beautiful designs, and rivaling genuine silver-plate in beauty of appearance.

German silver derives its name from the fact that

it was first made at Hildburghausen, in Germany, where it was made by smelting the ores of the metals above-mentioned, and a small proportion of iron ore also; this last, however, is very rarely used now, although it adds to the silvery whiteness of the alloy, but it renders it more brittle.

GERMAN TINDER. See AMADOU.

GERMA'NDER (*Teucrium*), a genus of plants of the natural order *Labiata*, having the calyx tubular, 5-toothed and sometimes 2-lipped; the

in a pungent volatile oil, has a camphor-like smell, and—like catmint and valerian root—has great attractiveness for cats. It is often used as a sternutatory; and its powder snuffed into the nose has proved very beneficial in cases of polypus.—A species found in Cochin-China (*T. thae*) is used there in infusion as tea.

GERMA'NIA was the general name under which the Romans designated not only great part of modern Germany, but also a portion of Belgium and the north and north-eastern districts of Gaul, the two last being more especially characterised as 'Germania Prima' and 'Secunda,' while Germany proper was also called 'Germania Magna,' 'Germania Trans-Rhenana,' or 'Germania Barbara.' The boundaries of the region comprehended under these designations were—on the west, the Rhine and Celtic Gaul; on the east, the Vistula and the Carpathian Mountains; on the south, the Danube; and on the north, the sea, which was divided by the Cimbrian Chersonesus (Jutland) into the German and the Suevic (Baltic) seas. The first occurrence in connection with the history of the people of G. with which we are acquainted, was the appearance of warlike tribes of Cimbri and Teutones in the present Steiermark or Stiria, where they defeated the Roman consul Papirius, in the year 113 B.C. Eleven years later, they again came into collision with the Roman arms, but the result was their signal defeat by Marius. The names Germani and Germania do not seem to have been appellations in use among the people themselves; and it is probable that the Romans borrowed them from the Gauls or Celts, in whose language the word 'gairm,' a loud cry (like the Homeric *boën agathōs*, 'good at the war-shout'), may possibly have served to designate this people, whose habit it was to accompany their attack on an enemy by loud cries. The Tungri were the first German people that crossed the Rhine, but other tribes soon followed; and when Julius Caesar opened his Gallic campaigns (58 B.C.), he found the Germanic nations of the Triboci, Nemetes, and Vangiones in possession of the districts lying between the left bank of the Rhine and the Vosges, while he even encountered a rival pretender to the supremacy of Gaul in the person of Ariovistus, the leader of the Suevic tribe of the Marcomanni. All these tribes were, however, finally reduced to subjection with the rest of Gaul, while the Tencteri and Usipetes, who had invaded Belgium, were driven, together with the Sicambri, across the Rhine to their former settlements by the victorious general, who for the first time (55 B.C.) led a Roman army into Trans-Rhenic Germany. The quiet which Caesar's victories had secured in the Rhenish districts was again so seriously disturbed by the Usipetes and several of the neighbouring tribes in the year 16 B.C., that Augustus, who had hastened to Gaul on the outbreak of disturbances, saw that stringent measures must be adopted to keep the Germans in check, and sent Drusus at the head of eight legions into Germany. The first step of the Roman general was to dig a canal ('fossa Drusiana') from the Rhine to the Yssel, by which the Roman galleys could sail from the heart of the continent to the ocean; and so successful were his measures, that in the course of four campaigns he had carried the Roman arms as far as the Albis (Elbe), subdued the Frisii, Batavi, and Chauci in the north, and defeated the Catti of the Moenus (Maine) districts. Drusus, who died 9 B.C., began the series of forts, bridges, and roads which were completed and extended under succeeding commanders. The attempt made by Varus, under the direction of Augustus, to introduce the Roman provincial forms

Germander, or Wood Sage (*Teucrium Scorodonia*):
a, corolla; b, calyx, with pistil.

corolla with the upper lip very short and bipartite, the lower lip spreading and trifid; the stamens much exserted. The species are numerous, and very widely distributed. A few are natives of Britain. The COMMON G. or WALL G. (*T. chamaedrys*), often found on ruined walls, has probably been introduced from the south of Europe. It is a small, almost shrubby, perennial; with wedge-shaped ovate inciso-serrate leaves, and whorls of about three large reddish purple flowers. It is bitter, somewhat aromatic, and was formerly much used in medicine, particularly in cases of gout. It was a principal ingredient in a once famous gout medicine called *Portland powder*.—Similar medicinal virtues were ascribed to *T. Botrys*, a small annual species common on dry hills in Germany; with aromatic fragrance and yellow flowers. WOOD G. or WOOD SAGE (*T. scorodonia*) is a very common British plant, growing in dry bushy or rocky places, with oblong-ovate very much wrinkled leaves, and one-sided racemes of yellowish-white flowers. It is very bitter and slightly aromatic. It is used in Jersey instead of hops.—WATER G. (*T. scordium*), a rare British species, growing in wet meadows, has a smell resembling that of garlic. It had once a great reputation in medicine.—CAT THYME (*T. Marum*), a native of the south of Europe, abounds

GERMANIA.

of administration into Germany, brought, however, a sudden check to the advance and consolidation of Roman power; for the tribes of Central Germany, indignant at this attempted subversion of their national institutions, ranged themselves under the leadership of Arminius, a chief of the Cherusci, who organised a general revolt. The result of this movement was the destruction at the *Salvus Teutobergensis* of the three legions commanded by Varus, and the subsequent loss of all the Roman possessions between the *Weser* and the *Rhine*. The news of this disastrous event threw the city of Rome into consternation. Germanicus, who was sent forth in 14 A. D. to restore Roman supremacy, would probably have again wholly subjugated the Germanic tribes had he not been recalled by Tiberius in the midst of his victories. From this time forth the Romans ceased their attempts to conquer Germany, and contented themselves with repelling the incursions which the tribes made on their frontiers, and endeavouring by their influence to foster the intestine disturbances which were perpetually generated through the ambition and jealousy of rival leaders, such as Arminius, Marbodius, and the Goth *Catualda*. After the murder of Arminius by his own people, the power of the Cherusci declined, while the *Longobardi* and *Catti* began to assert a recognised preponderance among the neighbouring tribes. Occasional encounters took place between the people of Central Germany and the legions who guarded the well-protected Roman boundary-line, which extended from the *Rhine* to the *Taunus*, and from thence to the *Danube*; and from time to time the *Batavii* and other warlike tribes of the north and north-west, who, like them, had been brought into partial dependence on the Romans, rose in formidable insurrection; but after Trajan had restored order and strengthened the forts, peace remained undisturbed in the north till the beginning of the 3d c., while, with the exception of the sanguinary war of the *Marcomanni* and *Quadi* under *Aurelius Antoninus* in the year 166 A. D., there was a similar absence of hostilities in the south. But with the 3d c. the tide of war turned, and the Romans were now compelled to defend their own empire from the inroads of the numerous Germanic tribes, foremost among whom stood the powerful confederacies of the *Alemanni* and *Franks*. In their track followed, during the next two centuries, successive hordes of the *Vandals*, *Suevi*, *Heruli*, *Goths*, and *Longobards*, who soon formed for themselves states and principalities on the ruins of the old Roman provinces. From this period till the establishment of the western empire in the person of *Charlemagne*, the history of Germany is a blank; but the condition of the country when he entered on the possession of his German patrimony, shewed that since the retirement of the Romans the lesser tribes had become gradually absorbed in the larger, for on his accession the land was held by a few great nations only, as the *Saxons*, *Frisians*, *Franks*, *Swabians*, and *Bavarians*, whose leaders exercised sovereign power within their own territories, and in return for military services, parcelled out their lands to their followers.

The knowledge which we possess of the habits and government of the ancient Germans is principally derived from the *Commentaries* of *Cæsar*, and the '*Germania*' of *Tacitus*; and imperfect as these sources of information are, they are infinitely less contradictory than the subsequent records of the earliest Christian times. According to the Roman historians, the Germans were a people of high stature, fair complexion, and red or yellow hair, endowed with great bodily strength, and distinguished for an indomitable love of liberty. The

men delighted in active exercises and the perils of war, and the women, whose chastity was without reproach, were held in high esteem. Each master of a family had absolute power over those of his household. Their habitations were generally separate, and surrounded by their several stalls and garners; for although there were villages whose inhabitants made common use of the fields and woods surrounding them, the Germans seem to have preferred isolated and detached dwellings to aggregate settlements. Towns and cities they long regarded with aversion, as inimical to personal freedom. In regard to their political organisation, it would appear that several villages formed a 'hundred,' several hundreds one 'gau,' and several gaus one tribe. In each tribe the people were divided into four classes—nobles, freemen, freedmen or vassals, and slaves. The king or chief was elected from among the nobles; but his power was very limited, and the government of the several tribes seems to have been democratic rather than monarchical.

The religion of the Germans, which is shrouded in great obscurity, points, like their language, to their eastern origin, and was based upon Asiatic myths of the creation of the world, and the existence of gods having the forms and attributes of a perfect humanity. Their conceptions of these mythical beings were modified by the local colouring which they received from association with new scenes, and through the lapse of time; and hence the different tribes had all their special gods or demigods, who were often their own leaders or chiefs, to whom the attributes of the god to whose worship they were most partial were ascribed. It is generally said that the Germans had neither temples nor statues. Both *Cæsar* and *Tacitus* expressly affirm this, but it cannot be regarded as literally true, for *Tacitus* himself mentions a temple of a goddess *Tanfana* among the *Marsians*; and at a later period, we find Christian missionaries exhorting the Germans to change their pagan temples into Christian churches, while we also read of the destruction of pagan idols. Nevertheless, the religion of the Germans was mainly carried on in the open air—in groves and forests, and on heaths and mountains. Although a priestly order also existed among the Germans, yet each master of a household performed religious services for himself and his family within his own homestead. A knowledge of the will of the gods and the events of the future was sought by divination from observations of the flight of birds, the rushing of waters, and other similar signs, in the interpretation of which women were thought to be especially skilled. Belief in a future life, and in an abode after death for those who had deserved well in this life, was cherished among the Germanic races, who had a strong faith in retributive justice, whose sway they believed would be extended over the gods by involving them in a universal annihilating conflict as the punishment of their evil deeds, after which a new world was to arise guarded by a pure and perfect race of gods. In addition to the higher deities, the Germans peopled every portion of space with a class of subordinate beings who pervaded the earth, air, and water, in the shape of elves, nixes, kobolds, dwarfs, and giants; while *Nornes* and *Valkuries* stood apart from either grade of spiritual existence as the representatives of destiny like the *Moiræ* and *Parcæ* of the Greeks and Romans.—See *Kuhn, Zur ältesten Gesch. d. indogerman. Völker* (Berlin, 1850); *Wackernagel, Familienleben d. Germanen* (Freibr. 1846); *Gibbon's Decline and Fall of the Roman Empire*; *Grimm, Deutsche Mythologie*

(1844); Müller, *Gesch. und System d. altheid. Religion* (1844).

GERMANICUS CÆSAR, a distinguished Roman general, belonging to the imperial family, was the son of Nero Claudius Drusus, and of Antonia, daughter of Mark Antony, and niece of Augustus. He was born 15 B.C., in the month of September. In accordance with the desire of Augustus, who had even thought of making him his successor, he was adopted in the year 4 A.D. by Tiberius, whom he accompanied in the war waged against the Pannonians and Dalmatians, for the purpose of securing the German frontiers after the defeat of Varus. After having been consul in 12 A.D., he was appointed in the following year to the command of the eight legions on the Rhine. On the death of Augustus, in 14 A.D., the soldiers revolted, demanding higher pay, and a shorter period of service. G. hastened from Gaul (where he happened to be at the time) to remind them of their duty. The soldiers, who almost idolised him for his frank and generous disposition, urged him to seize upon the supreme power. G., however, was incapable of treachery, and declared that he would rather die than forfeit his allegiance. He, however, granted their demands, though his colleague, A. Cæcina, secretly massacred the ringleaders at night. G. now led the legions over the Rhine below Wesel, attacked the Marsi during a nocturnal festival, and destroyed their celebrated temple of Tanfana. In 15 A.D., he made a second inroad into Germany. Proceeding from Metz into the country of the Catti, he destroyed their chief town of Mattium (Maden, near Gudensberg), slaughtering the entire inhabitants, young and old. On his return, his assistance was implored by the ambassadors of Segestes (always a firm ally of the Romans), who was besieged by his son-in-law, Arminius, the conqueror of Varus. This was at once given, and Thusnelda, the heroic wife of Arminius, fell into the hands of the Roman general. Arminius, burning with anger and shame, now roused the Cherusci and all the neighbouring tribes to war. G., in consequence, commenced a third campaign. He divided his army into three divisions. The main body of the infantry were led by Cæcina through the country of the Bructeri, the cavalry under another general marched through Friesland, while G. himself sailed with a fleet through the Zuydersee into the German Ocean, and proceeded up the river Ems, where he joined the others. The united divisions now laid waste the country in the neighbourhood of the Teutoburg forest, penetrated into its gloomy depths, and gathering up the bones of Varus and his legions, which had lain bleaching there for six long years, buried them with solemn funeral honours. A victory gained by Arminius induced G. to make a hasty retreat, during which he lost part of his fleet in a tempest. Cæcina, who retreated by land, sustained severe losses at the hands of the pursuing Germans. Before the fleet of 1000 vessels, which G. had built in Batavia, was equipped, he was recalled over the Rhine in 16 A.D. by news of the beleaguering of the recently acquired fortress of Aliso, on the Lippe. The Germans were repulsed, and the funeral mound in the forest of Teutoburg, which they had thrown down, was again erected. G. now sailed with his fleet again into the Ems, pressed forward to the Weser, which he crossed, and completely overthrew Arminius in two battles. Nevertheless, he determined to return, and on his way, again lost the greater part of his fleet in a great storm. In order to prevent this event from giving courage to the Germans, he once more, in the same year, marched into the country of the Marsi, and despatched his lieutenant, Silius, against the Catti.

The victories thus achieved were to have been followed up in the succeeding years, but Tiberius, jealous of his glory, recalled him, and feigning good-will, bestowed upon him the honour of a triumph, in which Thusnelda appeared among the captives. To rid himself of G., whose popularity seemed to render him dangerous, Tiberius sent him, in 17 A.D., with extensive authority, to settle affairs in the East, at the same time appointing Piso viceroy of Syria, whose haughty and despotic character everywhere counteracted the influence of Germanicus. G. died at Epidaphna, near Antioch, 9th October, 19 A.D., probably of poison. He was deeply lamented both by the inhabitants of the provinces and the citizens of Rome, whither his ashes were conveyed, and deposited by his wife Agrippina in the mausoleum of Augustus. Agrippina herself and two of her sons were put to death, by order of Tiberius; her third son, Caligula, was spared. Of the three daughters who survived their father, Agrippina became as remarkable for her vices as her mother had been for her virtues. Besides his splendid generalship, G. was conspicuous for his magnanimity, benevolence, finely cultured understanding, and personal purity of life. He wrote several works of a rhetorical character, which have been lost; but of his poetical works, we possess an epigram, a version of the *Phænomena* of Aratus, and fragments of a work of the same character, entitled *Diosemeia*, or *Prognostica*, compiled from Greek sources. G.'s literary remains were first published at Bologna, in 1474. The latest edition is that of Orelli, at the end of his *Phædrus* (Zurich, 1831).

GERMANO, SAN, a beautiful and prosperous town of Italy, is situated at the base of Monte Casino, in the province of Terra di Lavoro, about 50 miles north-north-west of Naples. It contains handsome public edifices, and is surrounded by the remains of monuments and buildings of high antiquarian interest; it is built on the site and from the ruins of the ancient Volscian town, Casinum, or Casca. The principal ruins of the ancient Volscian period are a monument, supposed to have been a tomb, an amphitheatre, and a temple. The first is now employed as a church; it is a square building, in the form of a Greek cross, constructed with enormous squared blocks of stone, on the Cyclopean principle. From its form, it is called the Church of the Crucifix, or *Crocifisso*. The second must have been a magnificent building, and it is still in a state of preservation sufficient to convey an idea of its original vast proportions. The third, adjoining the amphitheatre, was probably built in conjunction with it, at the cost of the Volscian matron, Umidia Quadratilla, mentioned by Pliny. The Benedictine monastery of Monte Casino, at a couple of miles' distance from San G., is one of the most renowned religious communities of Europe. Its foundation by St Benedict dates from 529. It contains one of the most beautiful churches of Italy, an extensive library, and a collection of the most precious documents of the middle ages in its valuable archives. The district surrounding San G. is highly cultivated, and beautiful. Pop. about 8000.

GERMANS, St, formerly the seat of the Episcopal government of the ancient diocese of Cornwall, England, now a small village in the county of Cornwall. It stands on the slope of a hill, on a branch of the river Lynher, 10 miles above Plymouth Sound, and 21 miles east-south-east of Bodmin. It is notable only for its fine parish church, which has an excellent Norman west front, and the towers of which are hung with ivy and fern. Pop. (1861) 2827.

GERMANTOWN, formerly a post-borough of North America, in the state of Pennsylvania, about

GERMANY.

6 miles north-north-west of Philadelphia, within the chartered limits of which city it was included in 1854. See article PHILADELPHIA.

GERMANY, from Lat. *Germania* (q. v.), is the English name of the country which the natives call Deutschland, and the French *L'Allemagne*. See **ALEMANNI**. It occupies the central portions of Europe, and extends from 6° 20' to 20° 10' E. long., and from 45° 5' to 54° 52' N. lat. It is bounded on the N. by the German Ocean, the Danish Peninsula, and the Baltic; on the E. by the extra-Germanic provinces of Prussia and Austria (viz., Prussia Proper and Posen, Galicia, Hungary, and Croatia), and by Russian Poland; on the S. by the Adriatic Sea, Italy, and Switzerland; and on the W. by France, Belgium, and the Netherlands. The population of Germany Proper is about 45,000,000. Its area is estimated at 280,000 square miles, or about $\frac{1}{10}$ th of that of all Europe. The coast-line measures about 730 miles, and the entire boundary-line about 2700 miles. G. is composed of an aggregation of different states (35 in number), which, as they are specially treated of under their respective heads, will only be noticed in the present article in as far as they severally form parts of the German Confederation.

The following list gives the names of these confederated states, with the amount of the contingent of men which each is bound to furnish (in accordance with the rate of its population) to the federal army. The populations and areas of the states will be found under *Europe* generally, and under the head of each specially.

Besides the above political divisions, there are certain distinctive appellations applied to different parts of G., which have been derived either from the names and settlements of the ancient Germanic tribes, or from the circles and other great subdivision of the old empire. Thus the name of 'Swabia' is still applied in common parlance to the districts embracing the greater part of Württemberg, Southern Baden, South-western Bavaria, and Hohenzollern; 'Franconia,' to the Maine districts of Bamberg, Schweinfurt, and Würzburg; 'the Palatinate,' to

Rhenish Bavaria and the north of Baden; 'the Rhineland,' to portions of Baden, Prussia, Bavaria, Hesse-Darmstadt, and Nassau; 'Voigtland,' to the high ground between Hof and Plauen; 'Thuringia,' to the districts lying between the Upper Saale and the Werra, as Saxe-Weimar, &c.; 'Lusatia,' to the eastern part of Saxony; 'East Friesland,' to the country between the Lower Weeser and Ems; and 'Westphalia,' to the district extending between Lower Saxony, the Netherlands, Thuringia, and Hesse, to the German Ocean.

Four-fifths of the population of this country are of the race called in English Germans, in French *Allemands*, but by the people themselves *Deutsche*. The term *Deutsch*, in Gothic *thiudisk*, in O. H. Ger. *diutisc* (Latinised into *theotiscus*), is derived from the Gothic substantive *thiuda*, people, and therefore meant originally the popular language, or, in the mouth of the learned, the vulgar tongue. In the 12th and 13th centuries it became elevated into the accepted designation both of this widespread tongue and of the race that speak it.

The whole population of the German Federal States amounted, at the close of 1857, as shewn by the census of that year, to upwards of 44,000,000. The most densely peopled districts were those about the cities of Trieste and Frankfurt-on-the-Maine, while the most sparsely peopled were those of Salzburg and the Tyrol and Carinthia generally. When considered in regard to origin, the population of G. may be divided as follows: Germans, 36,000,000; Slavonians, 7,343,000; Romanians, 530,000; Greeks and Armenians, 6000; Jews, 500,000. The Germans admit of being divided into High and Low Germans; the phraseology of the former is the cultivated language of all the German states, that of the latter, known as *Platt Deutsch*, is spoken in the north and north-west. The Slavonians are found chiefly in Austria, Prussia, and Saxony, and admit of being divided into a northern and southern branch. To the former belong the 'Czechs' of Bohemia, Moravia, and Silesia, the 'Wends' of Prussian Lusatia, the 'Water Polacks' of Silesia, and the 'Kassubes' of Pomerania; while to the latter branch belong the 'Slovenes' of Carinthia, the 'Croats' of Lower Austria and Moravia, and the 'Serbians' of Istria. The Romanic races comprise the Italians of Southern Tyrol, the Walloons and French in the Rhenish and Bavarian districts, the Ladinies of the Tyrol, the Furlani of Görz, and the Ostromanians of Carinthia and of the littoral districts of the south. Although the Jews are scattered over every part of Germany, they are most numerous in the Austrian and Prussian territories; while the few thousand gipsies settled on the German continent are almost exclusively limited to the south-eastern districts.

Physical Character.—G. may be regarded as presenting three distinct terrace-like formations—viz., 1. An alpine region in Southern Germany; 2. A range of high table-land which occupies the central portions of the continent; and 3. A vast sandy plain, which extends from the middle terrace to the German Ocean. The alpine region may be considered as lying south of a line drawn from Vienna to Bregenz, and embraces an area of about 42,000 square miles, covered with alpine heights and valleys. The central portion of G. as far north as a line drawn from Oderberg to Rheina on the Ems, having an area of about 105,000 square miles, consists of numerous ranges and groups of mountains (the Sudetic chain, Erzgebirge, Böhmerwald, Schwarzwald, Fichtelgebirge, Taunus, Hartz, &c.), and of table-lands and plains of greater or less elevation (e.g., the plateau of Bavaria between the Iller and the Inn, having a mean elevation of 1590

GERMANY.

feet; the mountainous table-land of the Rauhe Alp (see ALP) in Wurtemberg, &c.). The great plain of Northern G. extends from the Russian frontier to the Netherlands and Belgium, and has an area of about 94,500 square miles. The general low level of this plain is varied by two terrace-like elevations. The one stretches from the Vistula into Mecklenburg, at no great distance from the coast of the Baltic, and has a mean elevation of 500 to 600 feet, rising in one point near Danzig to 1020 feet; the other line of elevations begins in Silesia and terminates in the moorlands of Lüneburg, in Hanover, its course being marked by several summits from 500 to 800 feet in height. A large portion of the plain is occupied by sandy tracts interspersed with deposits of peat; but other parts are moderately fertile, and admit of successful cultivation.

In respect of drainage, the surface of G. belongs to four different basins. The Adige, and other streams of Southern Tyrol, carry the waters of 8000 square miles of G. into the Adriatic. The Danube (q. v.) from its source in the Schwartzwald to the borders of Hungary belongs to G., and through this channel the waters of 72,000 square miles are poured into the Black Sea; thus opening up communication with the east. The remaining part (two-thirds) of the surface has a northern slope, and belongs partly (122,000 square miles) to the basin of the North Sea, and partly (38,600 square miles) to the Baltic. The chief German streams flowing into the North Sea are the Rhine (q. v.), the Weser (q. v.), and the Elbe (q. v.); into the Baltic, the Oder (q. v.) and the Vistula (q. v.).

The most important of the numerous canals which connect together the great river systems of G. are Ludwig's Canal in Bavaria, which unites the Danube and Maine, and thus opens a communication between the Black Sea and German Ocean; the Wiener-Neustadt Canal in Lower Austria; the Finow and Friederick-Wilhelms' canals in Brandenburg; the Kiel and Eyder Canal, uniting the Baltic and German Ocean; and the Plauze Canal, which connects the Elbe and the Havel. Numerous lakes occur both in the elevated plains of Southern G. and in the low lands of the northern districts, but few of them are of any great size. The most important are the Boden-See (Lake of Constance) (q. v.); the Lake of Garda (q. v.), which, however, belongs only partially to G.; and the numerous smaller lakes which occur in the alpine districts of the Austrian provinces, and whose waters are dependent upon the mountain cascades. G. abounds in swamps and marsh-lands, which are especially numerous in the low northern districts and on the elevated plains of Moravia and Bavaria. Its mineral springs, of which there are probably nearly a thousand, occur principally in Bohemia, Nassau, Wurtemberg, Baden, and Bavaria. Many of these springs have retained their high reputation from the earliest ages.

Geology.—The Alps are raised by the intrusion of granitic rocks through Tertiary strata of the age of the Paris basin, which are elevated, often in a highly altered condition, on the sides of the mountains. These Tertiary strata continue northwards as far as the course of the Danube, covering the whole country from Berne to Vienna. The great plain of North Germany consists of strata of the same age, covered with very recent sand and mud. Newer Tertiary beds occupy the river basin of the Rhine north from Mayence; they consist of fine light-coloured loam, and contain the bones of the mammoth, rhinoceros, and other contemporaneous mammals. Erratics are scattered over the north of Germany. The whole district in the centre of

Germany, from the Danube northwards to Hanover, consists of Secondary strata. The rocks of the Trias period are best known in Germany, the typical rocks of bunter sandstein, muschel-kalk, and keuper being developed here, so as to justify the suitability of the name Trias, which is wholly inapplicable in Britain, where the series is represented by sandstone beds only. In Southern Germany the strata of this age are rich in mines of rock-salt. The Trias is highly fossiliferous, abounding especially in marine shells, and containing several genera of remarkable labyrinthodont saurians. Jurassic rocks occur in Central Germany; at Hanover they consist of clays and marl, with beds of sandstone and limestone, containing coal and ironstone of such value that they have been extensively wrought. The Cretaceous strata are frequently highly altered from the intruded igneous rocks, which have raised the beds in some districts to a nearly vertical position, and have altered them into crystalline marbles and silicious sandstones.

Of the Palaeozoic rocks, the carboniferous strata are nearly absent in Germany. The coal obtained in the country is from rocks of a later age. True coal-beds are found in Rhenish Prussia. The sedimentary rocks of the Hartz Mountains are chiefly Devonian; to the south-east, near Herzgerode, they are Upper Silurian. They are all greatly dislocated by granite and other intrusive rocks. The Hartz Mountains are surrounded by a zone of Permian rocks. The stratified rocks of the Thuringerwald are also Devonian, resting on Lower Silurian strata, the lower portion of which is highly altered into quartzose schists; the remainder consists of greywacke, slate, and sandstone, with limestone and alum slates. There are numerous fucoid and annelid impressions in the older beds, and graptolites, orthoceratites, and trilobites in the newer.

The granitic rocks appear in the Alps, the Riesengebirge, and Erzgebirge. The basalts, trachytes, and other volcanic products are largely developed in the Eifel, Siebengebirge, Westerwald, Vogels, Rhön-gebirge, and other mountain systems.

Climate.—The climate of G. presents less diversity than a first glance at the map might lead one to infer, for the greater heats of the more southern latitudes are considerably modified by the alpine character of the country in those parallels, while the cold of the northern plains is mitigated by their vicinity to the ocean. The average decrease in the mean temperature is in going from south to north, about 1° F. for every 52 miles; and in going from west to east, about 1° F. for every 72 miles. The line of perpetual snow varies from 7200 to 8000 feet above the level of the sea. The mean annual fall of rain is 20 inches; the maximum, which is met with on the southern slope of the Alps, being 28 inches. The following table shews the mean annual records of the temperature at different points of the continent:

	Mean An. Temp.	Summer.	Winter.
Trieste,	55° Fah.	72° Fah.	36° Fah.
Vienna,	49.5	70	29
Hamburg,	47°	64	30
Dresden,	48°	67	29
Frankfort-on-the-Maine, .	46.5	66	31
Berlin,	46.5	66	27
Hanover,	46°	63	33
Königsberg,	43°	62	24

Products.—G. is rich in mineral products, among which the most important are silver, found in the Hartz Mountains; quicksilver, lead, copper, and tin in the Austrian provinces especially; iron in numerous mountain-ranges; salt in many parts of the country; coal in Rhenish Prussia, Silesia, Bohemia, and Styria. Cobalt, arsenic, sulphur, saltpetre,

GERMANY.

alum, gypsum, bismuth, pumice-stone, tripoli-slate, kaolin, emery, ochre, and vitriol, are all among the exports of Germany. The vegetable products comprise a very large proportion of the European flora. All the ordinary cereals are extensively cultivated in the north, and largely exported, chiefly from Württemberg, Bavaria, and Moravia; hemp and flax, madder, woad, and saffron, grow well in the central districts, where the vine, the cultivation of which extends in suitable localities as far north as 51°, is brought to great perfection—the best wine-producing districts being the valleys of the Danube, Rhine, Maine, Neckar, and Moselle, which are, moreover, generally noted for the excellence of their fruits and vegetables. Tobacco is grown in sufficient quantities for extensive exportation on the Upper Rhine, the Werra, and Oder. The hops of Bohemia and Bavaria have a high reputation, and the chicory grown in those countries, and in the district between the Elbe and Weser, finds its way all over Europe as a substitute for coffee. The most extensive forests are found in Central and Southern G., and in some parts of Prussia, while the north-western parts of the great plain are deficient in wood, the place of which is in some degree supplied by the abundance of turf yielded by the marshy lands. G. has long been noted for the good breed of horses raised in the northern parts of the continent, while Saxony, Silesia, and Brandenburg have an equal reputation for their sheep-flocks, and the fine quality of the wool which they yield. The rich alluvial flats of Mecklenburg and Hanover are celebrated for their cattle; the forests of Northern and Central G. abound in swine, and in small game of various kinds; while the Bavarian and Austrian Alps afford shelter to the larger animals, as the chamois, the red deer and wild-goat, the fox, marten, and wolf, and even in some parts to the bear and lynx. The eagle, vulture, and other birds of prey are met with in these alpine regions; and in all the plains in the north, storks, wild-geese, and ducks are abundant. Among the fishes of G., the most generally distributed are carp, salmon, trout, and eels; the rivers contain also cray-fish, pearl-bearing mussels, and leeches. The oyster, herring, and cod fisheries, constitute important branches of industry on the German shores of the Baltic and North Sea. G. stands next to Great Britain in regard to the care and success with which its agricultural, mining, and other natural capabilities have been cultivated. All the German states encourage agriculture, and have endeavoured, by the establishment of agricultural colleges and exhibitions, to diffuse among the people a knowledge of recent scientific appliances. The countries which have become most conspicuous in this movement are Lower Austria, Moravia, Silesia, Bohemia, Bavaria, and Saxony. The preservation and cultivation of woods receive almost as much attention in G. as agriculture, and like the latter, are elevated to the rank of a science. The larger woods and forests in most of the states belong to the government, and are under the care of special boards of management, which exercise the right of supervision and control over all forest lands, whether public or private.

The following table shews, approximately, the relative modes of distribution of the country into arable, meadow, and other lands, heaths, &c., reckoning the Prussian *morgen* = $\frac{1}{63}$ of an acre:

	Acre.
Arable land,	60,742,710
Meadow land,	16,131,570
Gardens, orchards, &c.,	1,779,130
Vineyards,	691,929
Woods, forests,	40,306,140
Heaths, moors, roads, buildings, &c.,	28,673,968
	148,544,537

Manufactures.—The oldest and most important of the German industrial arts are the manufactures of linen and woollen goods. The chief localities for the cultivation and preparation of flax, and the weaving of linen fabrics, are the mountain-valleys of Silesia, Northern Bohemia, Moravia, Lusatia, Westphalia, the Hartz, and Saxony (for thread-laces); while cotton fabrics are principally made in Rhenish Prussia, Saxony, Moravia, and Lower Austria. The same districts, together with Pomerania, the Tyrol, and Bavaria, manufacture the choicest woollen fabrics, including damasks and carpets. Toys, wooden clocks, and wood-carvings, which may be regarded as almost a speciality of German industry, are carried to the greatest perfection in the hilly districts of Saxony, Bavaria, the Black Forest, and the Tyrol. The best iron and steel manufactures belong to the Austrian provinces, Silesia, Hanover, and Saxony. Bohemia and Silesia probably possess the finest glass-manufactories; while Saxony, Prussia, and Austria stand pre-eminent for the excellence of their china and earthen wares. Prague, Augsburg, and Nürnberg dispute with Vienna, Munich, and Berlin the title to pre-eminence in silver, gold, and jewellery work, and in the manufacture of philosophical and musical instruments; while Leipsic, together with Vienna and Munich, claims the first rank for its type-foundries, printing, and lithography. The trading cities of Northern G. nearly monopolise the entire business connected with the preparation of tobacco, snuff, &c., the distillation of brandies, and the manufacture of sugar from the beet, potato, and other roots; while vinegar and oils are prepared almost exclusively in Central and Southern Germany.

Exports and Imports.—The chief exports of G. are linen, woollen-cloth, wool, grain, seeds yielding oil, wooden goods, toys, glass and earthen-ware, leather, horn, bristles, honey, wax, wine, spirit, zinc, cobalt, gypsum, potash, vitriol, copper, brass, iron, and steel ware. The principal imports are raw cotton and silk, the ordinary articles of colonial produce, as sugar, rice, &c., tea, spices, furs, pitch, train-oil, dried fish, &c. According to Dr Hübner, the value of the imports and exports which passed the German customs between 1850 and 1855 exhibits the following rates of increase, given in German thalers:

Year.	Imports. Thalers.	Exports. Thalers.	Transit. Thalers.	Sum total. Thalers.
1850,	181,669,164	179,948,116	78,994,480	439,831,760
1853,	208,931,989	251,380,676	105,509,459	565,822,124
1855,	315,764,875	308,567,411	167,036,000	791,368,286

While, according to Dr Brachelli's *Statistische Tabellen* for 1862, the imports of the Zollverein for 1861 were 312½ million thalers, and the exports 350½ million thalers. The principal German ports are Hamburg and Bremen, for American and British commerce; Trieste, for the Mediterranean and Oriental trade; Altona, Lübeck, Stettin, and Stralsund, for general trade. The chief emporiums for inland commerce are Augsburg and Botzen, for Italy; Augsburg, Constance, and Memmingen, for Switzerland; Frankfurt-on-the-Maine and Mayence, for France; Aix-la-Chapelle and Cologne, Leipsic and Frankfurt-on-the-Oder, for Russia. The home-trade is principally effected in the south-east by Vienna; in the south-west, by Augsburg; in the north-west, by Frankfurt-on-the-Maine; and in the north-east, by Leipsic; while Berlin, Cologne, Nürnberg, Prague, Breslau, Mayence, and Frankfurt-on-the-Oder, are all important centres of the general home-trade. The great periodic fairs, which are still held in different cities, as at both the Frankfurts, Brunswick, Stuttgart, Leipsic, &c., constitute no unimportant adjuncts to the commerce of Germany. The book-fairs held

at the two last-named cities—the only ones of their kind in Europe—may be regarded as the two great centres of the German book-trade, Leipzig supplying the north, and Stuttgart the south of the continent. The maritime trade of G. has of late years attained very great importance. There were in 1858, according to Dr Brachelli, about 5000 German sea-going vessels (exclusive of about 900 or 1000 steam and sailing coast and river boats); while about 100,000 vessels yearly enter the German ports.

The railways, which intersect each other in all directions from Trieste to Hamburg, and from Vienna to Aix-la-Chapelle, measure, in 1862, nearly 1800 German, or about 7250 English miles; while according to Brachelli, the high-roads of G. extended over a length of 27,000 German miles. The postal system of the German states, which is administered by 18 Boards of Control, includes the expedition of passengers and goods by the post-carriages of the several departments. Since 1851, in accordance with a treaty concluded between Austria and Prussia, a Germano-Austrian postal confederation has been established, the objects of which are to secure an effective and more energetic administration of the various branches of the organisation, and the adoption of a uniform scale of charges, while it likewise exercises the duty of concluding international postal treaties with foreign states. A similar confederation, representing all the principal German states, controls the administration of the telegraphic lines, which measure nearly 5000 German miles.

The multiplicity of small states, into which the German land is broken up, has opposed great obstacles to the development of commerce; but the difficulty has to some extent been obviated by the establishment of the *Zoll und Handels-verein* (q. v.), or 'Customs and Trade Confederation.'

Education.—Education is more generally diffused in G. than in any other country of Europe, and is cultivated with an earnest and systematic devotion not met with, to an equal extent, among other nations. There are 24 universities: Vienna, Prague, Grätz, Innsbruck, Berlin, Breslau, Halle, Bonn, Greifswald, Olmütz, Munich, Würzburg, Erlangen, Leipzig, Tübingen, Göttingen, Heidelberg, Freiburg, Marburg, Giessen, Jena, Rostock, Kiel, and Königsberg. These institutions embrace the four faculties of theology, law, medicine, and philosophy, and have between 1700 and 1800 professors, and on an average about 14,000 students. There are also 16 polytechnic institutions; upwards of 500 high schools or gymnasia; numerous special schools of technology, agriculture, commerce, military science, &c.; several seminaries for teachers, and for the ministers of different religious denominations; and 62,000 free national schools. The attendance of children at school, for at least four or five years, is made compulsory in nearly all the German states, and hence the proportion of persons who cannot read and write is exceedingly small in Germany.

Public libraries—of which there are more than 150—museums, botanical gardens, art-collections, picture-galleries, schools of music and design, and academies of arts and sciences, are to be met with in most of the capitals, and in many of the country towns, upwards of 200 of which possess one or more permanently established theatres. In no country is the book and publishing trade more universally patronised than in Germany. The press annually sends forth from 8000 to 10,000 works, while about 3000 papers and journals are circulated throughout the confederate states; of the current newspapers, a comparatively small number only exert any marked influence, but many of the German scientific and literary periodicals enjoy a world-

wide reputation. The censorship of the press was abolished by a decree of the diet of 1848, and freedom of the press, under certain restrictions, which were promulgated in 1854, has been introduced in all the confederate states.

Religion.—In regard to religion, it may be stated generally that Protestantism predominates in the north, and Roman Catholicism in the south, although very few states belong exclusively to either form of faith.

The following is the proportion of the different denominations, as given by Dr Brachelli: Roman Catholics, 22,300,000; Lutherans, 10,200,000; Calvinists (Evangelical), 9,300,000; Calvinists (Reformed), 900,000; various Christian sects, as Herrenhutens, Mennonites, &c., 50,000; Greek and Armenian Church, 5000; Jews, 500,000.

Political Organisation.—All the states of the Confederation recognise four distinct orders—viz, the nobility, clergy, burghers, and peasantry, and all distinguish three distinct grades of nobility. The highest of these includes the members of reigning houses, and the descendants of families who belonged at the time of the old empire to the sovereign nobility of the state, and were *reichsunmittelbar*, or directly connected with the empire, as holding their domains directly under the emperor, but whose houses have subsequently been *mediatised*, or deprived of sovereign power in accordance with special treaties between the state and the princes. There are at present 50 princely and 51 *gräfliche* (countly) *mediatised* families, who, in accordance with the act of the diet of 1806, have equality of rank with reigning houses, and enjoy many of the special privileges which were accorded to the high nobles of the empire. The second grade of nobility is composed of counts and barons not belonging to reigning or *mediatised* houses, whilst the third and lowest grade includes the knights and hereditary patrimonial proprietors of Germany.

Before we proceed to consider the political organisation of the existing Confederation, we will briefly describe the principal features of the constitution of the old German empire, on which the present system of the federal government has been based. (The origin of the empire is described in the historical sketch below.) The states of the empire consisted of three chambers or colleges. 1. The Electoral College, which consisted of the archiepiscopal electors of Mainz, Treves, and Cologne; and the secular electors, of which there were originally only four, but whose number was subsequently increased to five, and who at the dissolution of the empire were represented by the sovereigns of Bohemia, Bavaria, Saxony, Brandenburg, and Brunswick-Lüneburg or Hanover (see ELECTORS). 2. The College of the Princes of the Empire, who had each a vote in the diet, and were divided into spiritual and temporal princes. 3. The Free Imperial Cities which formed a college at the diet, divided into two benches, the Rhenish with 14 cities, and the Swabian with 37; each of which had a vote. These colleges, each of which voted separately, formed the diet of the empire. When their respective decisions agreed, the matter under discussion was submitted to the emperor, who could refuse his ratification of the decisions of the diet, although he had no power to modify them. Ordinary meetings were usually summoned twice a year by the emperor, who specified the place at which the sittings were to be held, and which, during the latter periods of the empire, were at Regensburg (Ratisbon). The diet had the right to enact, abrogate, or modify laws, conclude peace and declare war, and impose taxes for the general expenses of the state. The

GERMANY.

Aulic Chamber, and the Cameral or chief tribunal of the empire, decided in cases of dispute between members of the diet. The emperors were elected by the electors in person or by their deputies; and after their election and coronation, which usually both took place at Frankfurt-on-the-Maine, the emperor swore to the 'capitulation' or constitution of the empire. The diet, after the dissolution of the empire in 1806, remained in abeyance till it was re-organised in 1814, after the disruption of the Confederation of the Rhine, which had owed its existence to Napoleon.

The existing Germanic Confederation was established by an act of the Congress of Vienna in 1814, and confirmed by a further act in 1821. It is an indissoluble union, from which no single state can at its own pleasure retire. Its central point and its executive and legislative powers are represented by the federative diet, which holds its meetings at Frankfurt-on-the-Maine, and is composed of delegates from all the confederate states, chosen not by the people, but by the various governments. The diet deliberates either in a limited council (the Federative Government) or as a general assembly (*Plenum*). In the limited council there are 17 votes, of which 11 of the principal states have each a single vote, while the remaining states divide the six collective votes between them. The *Plenum*, which meets only when any organic change is to be effected in the diet itself, embraces 70 votes, of which Austria and the five German kingdoms have each four, while the other states have 3, 2, or 1 vote each in proportion to their individual importance. It rests with the limited council, which executes the enactments of the *Plenum*, and despatches the ordinary business of the Confederation, to decide (by a majority of voices) whether a question shall be submitted to the *Plenum*, where it is not debated, but simply decided by a majority of ayes or noes. Austria presides in both assemblies, and has a casting voice in cases of equality. The diet, as a collective body, has the right of concluding peace and alliances, and declaring war; but this power can only be exercised for the maintenance of the independence and external security of G., and the individual integrity of the several federative states, which on their part are bound to submit to the diet the consideration of all questions in dispute between themselves and other powers. Where such differences cannot be settled by the committee empowered by the *Plenum* to consider them, they are finally referred to a special tribunal known as the 'Austriacal' Court, which is composed of several members of the Confederation invested for the time with full powers. The diet is bound to maintain the existing order of government in each state, and to aid the sovereign in suppressing any attempts by the subjects to subvert it. Those members of the Confederation whose territories do not contain a population of 300,000, must, in accordance with the rules of the diet, incorporate themselves with some other federative state for the establishment of a joint high court of appeal. When disputes arise between rulers and their subjects in regard to the questions of internal government, they must be submitted to the tribunal of the federative government, which is a body composed of 34 members, known as *Spröckmänner*, who are elected triennially by the diet, and from among whom the disputing parties choose their respective umpires. The army of the Confederation, which is composed, as already stated, of the contingents furnished by the different states in proportion to their respective populations, amounts to nearly 563,000 men on a war-footing, and 503,000 on a peace-footing. More than half this number is

supplied by the contingents of Austria and Prussia on whose troops devolves the duty of garrisoning the fortress of Mayence, and (in conjunction with Bavarian troops) the city of Frankfurt-on-the-Maine, as the seat of the diet. The finances of the diet are under the control of a financial committee, which fixes the proportion to be paid into the common treasury by each state in accordance with the number of its inhabitants.

German History.—After the gradual expulsion or retirement of the Romans from Germany, the country necessarily became subdivided into numerous petty states, each governed by its own chief. The erection of the Franko-Merovingian empire in France had given preponderance to the Frankish power on both sides of the Rhine, and when Charlemagne succeeded in 771 to the German as well as the Gallic possessions of his father, Pepin d'Heristal, he found himself possessed of an amount of territory and a degree of influence which speedily enabled him to assert supremacy over the whole of the west of Germany, while his conquests over the heathen Saxons in the north, and the Avari who then held Pannonia in the south-east, extended his German dominions from the North Sea to the Alps, and from the Rhine as far as Hungary. With Charlemagne, who received the imperial crown at the hands of the pope in 800, began the long line of emperors and kings who occupied the German throne for more than a thousand years, and with him, too, the vast fabric, which he had reared on the ruins of Roman power, lost its stability, for at his death in 814, no member of his family was competent to wield the imperial sceptre, although in 843 some portions of his German possessions fell, in accordance with a family compact, to his grandson Ludwig, surnamed 'the German,' who was recognised as king of Germany. On the extinction, in 911, of the degenerate Carolingian dynasty in the person of Ludwig 'the Child,' the provincial rulers, who, together with the archbishops, bishops, and abbots, constituted the chief members of the diet or national assembly, arrogated to themselves (in imitation of the practice of the nobles of the ancient German tribes) the right of electing their sovereign, who, however, could not assume the imperial title till he had been crowned by the pope. At this period, there were in Germany five nations—the Franks, Saxons, Bavarians, Swabians, and Lorrainers. The Franks, as the descendants of those who had conquered the land and founded the empire, enjoyed a pre-eminence over the others; and hence, on the extinction of the Carolingian race, the choice of the prince-electors seems to have fallen almost as a matter of course on the chief of the Franks, the Duke or Count of Franconia, who reigned as king of Germany from 911 to 918, under the title of Conrad I. At his own instigation, his rival and adversary, Henry, Duke of Saxony, was chosen as his successor, and proved himself an able and warlike prince. The conquests which he gained over the Danes, Slaves, and Magyars were confirmed and extended by his son and successor,

Otho I. (936-1073), who carried the boundaries of the empire beyond the Elbe and Saale, and who, by his acquisition of Lombardy, laid the foundation of the relations which existed for many ages between the rulers of Germany and the Italian nation. Otho's coronation-festival was eventful, as it formed the precedent for the exercise of those offices which, till the dissolution of the empire, were regarded as connected with the dignity of the secular electors, for on that occasion, while the emperor dined with his three spiritual electors, he was waited upon by the secular princes—the Elector of Bavaria (afterwards Saxony) serving as grand-marshal; of Swabia (afterwards Bohemia), as grand-cupbearer; and of Lorraine (afterwards Brandenburg), as arch-chamberlain.

Otho II. (973-983), Otho III. (983-1002), and Henry II. (1002-1024), belonged to the House of Saxony, which was succeeded by that of Franconia, in the person of Conrad II. (1024-1039), an able ruler, who added Burgundy to the empire. His son and successor, Henry III. (1039-1056), extended German supremacy over Hungary, part of which he conquered and annexed to Lower Austria, while he repressed the insolence and despotism of the temporal and spiritual princes of Germany, and gained the respect of his contemporaries by his zeal for justice and his valour in the field. The minority of his son and successor, Henry IV. (1056-1106), enabled the nobles to recover much of their former power, and to apply a check to the further consolidation of the imperial authority, which had been considerably extended under the two preceding reigns. Henry's constant quarrels with the astute Gregory VII. entangled him in difficulties and mortifications which only ended with his life, and which plunged Germany into anarchy and disorder, and entailed upon the empire destructive wars which convulsed the whole of continental Europe for more than two centuries. With his son and successor, Henry V. (1106-1125), the male line of the Franconian dynasty became extinct; and after the crown had been worn (1125-1138) by Lothaire of Saxony, who made a bold attempt to recover some of the prerogatives of which at his election the empire had been deprived through papal intrigues, the choice of the electors, after a season of dissension and intrigue, fell upon Conrad III., Duke of Franconia, the first of the Hohenstauffen dynasty (1138-1152). His reign, in which the civil wars of the Guelphs and Ghibellines began, was distracted by the dissensions of the great feudatories of the empire, while the strength of Germany was wasted in the disastrous Crusades, in which Conrad took an active part. On his death, the electoral college for the first time met at Frankfurt, which retained the honour of being the place at which the sovereign was elected and crowned till the dissolution of the empire in the 19th century. Frederick I. (1152-1190), surnamed Barbarossa, Duke of Swabia, was, at the recommendation of his uncle Conrad, chosen as his successor, and the splendour of his reign fully warranted the selection. By the force of his character, Frederick acquired an influence over the diets which had not been possessed by any of his immediate predecessors, and during his reign many important changes were effected in the mutual relations of the great duchies and counties of Germany, while we now for the first time hear of the *hereditary* right possessed by certain princes to exercise the privilege of election. Unfortunately for Germany, this great monarch suffered the interests of his Italian dominions to draw him away from those of his own country, whilst his participation in the Crusades, in which both he and the flower of his chivalry perished, was only memorable

for the misfortunes which it entailed on the empire. The interval between the death of Frederick Barbarossa (1190) and the accession of Rudolf I. (1273), the first of the Hapsburg line, which, through a female branch, still reigns in Austria, was one of constant struggle, internal dissension, and foreign wars. Individually, the princes of the Hohenstauffen dynasty were popular monarchs, their many noble and chivalrous qualities having endeared them to the people, while one of the race, Frederick II. (1212-1250), was, after Charlemagne, perhaps the most remarkable sovereign of the middle ages; but their ambitious designs on Italy, and their constant but futile attempts to destroy the papal power, were a source of misery to Germany, and with Frederick II. ended the glory of the empire, till it was partially revived by the Austrian House of Hapsburg. His son, Conrad IV. (1250-1254), after a brief and troubled reign, was succeeded by various princes, who, in turn, or in some cases contemporaneously, bore the imperial title without exercising its legitimate functions or authority. This season of anarchy was terminated at the accession of Rudolf I. (1273-1291), who, by the destruction of the strongholds of the nobles, and the stringent enforcement of the laws, restored order. His chief efforts were, however, directed to the aggrandisement of his Austrian possessions, which embraced Styria, Carinthia, Carniola, and Tyrol.

For the next 200 years, the history of the German empire presents very few features of interest, and may be briefly passed over. Adolf of Nassau, who was elected to succeed Rudolf, was compelled in 1298 to yield the crown to the son of the latter, Albrecht I. (1298-1308), whose reign is chiefly memorable as the period in which three Swiss cantons, Unterwalden, Schwytz, and Uri, established their independence. After the murder of Albrecht, the throne was occupied in rapid succession by Henry VII. (1308-1313), who added Bohemia to the empire; and conjointly by Frederick of Austria and Ludwig of Bavaria (1313-1349). Charles IV. (1349-1378) of Luxembourg was the successful candidate among many rivals, and although he attended specially to the interests of his hereditary possessions of Bohemia, Moravia, Silesia, and Lusatia, he did not entirely neglect those of the empire, for which he provided by a written compact, known as the *Golden Bull*, which regulated the rights, privileges, and duties of the electors, the mode of the election and coronation of the emperors, the coinage, customs, and commercial treaties of the empire, and the rights and obligations of the free cities. His son, Wenceslaus (1378-1400), who was finally deposed, brought the royal authority into contempt, from which it was scarcely redeemed by Ruprecht of the Palatinate (1400-1410). The nominal reign of Sigismund (1410-1437), the brother of Wenceslaus, would demand no notice were it not for his connection with the Councils of Constance and Basel, at the former of which Huss was condemned, and which was followed by the disastrous Hussite wars. The readiness with which Sigismund lent himself to the interests of Henry V. of England, and of all other princes who ministered to his love of personal display, brought discredit on the imperial dignity, while his dishonourable desertion of Huss will ever attach ignominy to his name. Albrecht II. of Austria (1438-1440), after a brief reign of two years, in which he gave evidence of great capacity for governing, was succeeded by his cousin, Frederick III. (1440-1493), an accomplished but avaricious and indolent prince, whose chief object seemed to be the aggrandisement of the House of Austria, with which the title of

GERMANY.

emperor had now become permanently connected (see AUSTRIA), while he neglected the interests of Germany collectively, and suffered the infidels to make unchecked advances upon its territory. Maximilian I. (1493—1519), the son and successor of Frederick, resembled him in few respects, for he was active, ambitious, and scheming, but deficient in steadiness of purpose. His marriage with Mary, the rich heiress of her father, Charles the Bold of Burgundy, involved him in the general politics of Europe, while his opposition to the reformed faith preached by Luther exasperated the religious differences which disturbed the close of his reign. Maximilian had, however, the merit of introducing many improvements in regard to the internal organisation of the state, by enforcing the better administration of the law, establishing a police and an organised army, and introducing a postal system. With him originated, moreover, the special courts of jurisdiction known as the 'Imperial Chamber' and the 'Aulic Council'; and in his reign, the empire was divided into ten circles, each under its hereditary president and its hereditary prince-convoker. Maximilian lived to see the beginning of the Reformation, and the success that attended Luther's preaching; but the firm establishment in Germany of the reformed faith, and the religious dissensions by which its success was attended, belong principally to the reign of his grandson, Charles I., king of Spain, the son of the Archduke Philip and of Joanna, the heiress of Spain, who succeeded to the empire under the title of Charles V. (1519—1556). The management of his vast possessions in Spain, Italy, and the Netherlands, and the wars with France, in which he was so long implicated, diverted him from his German territories, which he committed to the care of his brother Ferdinand. The princes of Germany were thus left to settle their religious differences among themselves, and to quell, unaided by the head of the state, the formidable insurrection of the peasants (1525), which threatened to undermine the very foundations of society. This rising of the lower orders was due to the preaching of the fanatic Münzer, and other leaders of the sect of Anabaptists, which had arisen from a perverted interpretation of some of the tenets advanced by Luther. Charles's determined opposition to the reformers rendered all settlement of these religious differences impracticable; and although, by the aid of his ally, Maurice of Saxony, he broke the confederation of the Protestant princes, known as the Union of Smalkald, he was forced by his former ally to make concessions to the Lutherans, of which he disapproved; and in his disgust at the complicated relations in which he was placed to both parties, he abdicated in favour of his brother Ferdinand (1556—1564), who put an end to much of the religious dissension that had hitherto distracted the empire, by granting entire toleration to the Protestants. Although Ferdinand was, personally, mild and pacific, his reign was troubled by domestic and foreign aggressions—the different sects disturbing the peace of the empire at home, while the French and the Turks assailed it from abroad. During the next fifty years, the empire was a prey to internal disquiet. Maximilian II. (1564—1576) was indeed a wise and just prince, but the little he was able to effect in reconciling the adherents of the different churches, and in raising the character of the imperial rule, was fatally counteracted by the bigotry and vacillation of his son and successor, Rudolf II. (1576—1612), in whose reign Germany was torn by the dissensions of the opposite religious factions, while each in turn called in the aid of foreigners to contribute towards the universal anarchy which culminated in the Thirty

Years' War, begun under Rudolf's brother and successor Matthias (1612—1619); continued under Ferdinand II. (1619—1637), an able, but cruel and bigoted man; and ended under Ferdinand III. (1637—1657), by the treaty of Westphalia, in 1648. The effect of the Thirty Years' War was to depopulate the rural districts of Germany, destroy its commerce, burden the people with taxes, cripple the already debilitated power of the emperors, and cut up the empire into a multitude of petty states, the rulers of which exercised almost absolute power within their own territories. Leopold I. (1658—1705), a haughty, pedantic man, did not avail himself of the opportunities afforded by peace for restoring order to the state, but suffered himself to be drawn into the coalition against France, whilst his hereditary states were overrun by the Turks. Although success often attended his arms, peace brought him no signal advantages. The reigns of Joseph I. (1705—1711) and Charles VI. (1711—1740), with whom expired the male line of the Hapsburg dynasty, were signalised by the great victories won by the imperialist general, Prince Eugene, in conjunction with Marlborough, over the French; but they brought no solid advantage to the empire. The disturbed condition of Spain and Saxony opened new channels for the interference of Germany, which was further distracted, after the death of Charles, by the dissensions occasioned by the contested succession of his daughter, Maria-Theresa, and, through her, of her husband, Francis I. of Lorraine (1745—1765), after their rival, the Bavarian Elector, Charles VII., had, through the intervention of Prussian aid, been elected in 1742 to the imperial throne, which, however, he was obliged to cede, after a brief occupation of three years. Constant disturbances, intensified during the Seven Years' War, when Frederick the Great of Prussia maintained his character of a skilful general at the expense of the Austrians, made the reign of these sovereigns one of trouble and disaster. Joseph II., their son (1765—1790), during the lifetime of Maria-Theresa, who retained her authority over all the Austrian states, enjoyed little beyond the title of emperor, to which he had succeeded on his father's death. But when he ultimately acquired his mother's vast patrimony, he at once entered upon a course of reforms, which were, however, premature, and unsuited to the cases to which they were applied; whilst his attempts to re-establish the supremacy of the imperial power in the south of Germany were frustrated by Prussian influence. Leopold II., after a short reign of two years, was succeeded in 1792 by his son, Francis II., who, after a series of defeats by the armies of the French republic, and the adhesion, in 1805, of many of the German princes to the alliance of France, which led to the subsequent formation of the Rhenish Confederation under the protectorate of Napoleon, resigned the German crown, and assumed the title of Emperor of Austria. From this period till the Congress of Vienna of 1814—1815, Germany was almost entirely at the mercy of Napoleon, who deposed the established sovereigns, and dismembered their states in favour of his favourites and dependants, while he crippled the trade of the country, and exhausted its resources by the extortion of subsidies or contributions. As a reconstruction of the old empire was no longer possible, those states which still maintained their sovereignty combined, in 1815, to form a German Confederation. Of the 300 states into which the empire had once been divided, there now remained only 40, a number which has since been reduced to 35 by the extinction of several petty dynasties. The diet was now reorganised, and appointed

to hold its meetings at Frankfurt-on-the-Maine, after having been formally recognised by all the allied states as the legislative and executive organ of the Confederation; but it failed to satisfy the expectations of the nation, and soon became a mere political tool in the hands of the princes, who simply made its decrees subservient to their own efforts for the suppression of every progressive movement. The French revolution of 1830 reacted sufficiently on some few of the German states to compel their rulers to grant written constitutions to their subjects; but the effect was transient; and it was not till 1848 that the German nation gave expression, by open insurrectionary movements, to the discontent and the sense of oppression which had long possessed the minds of the people. The princes endeavoured, by hasty concessions, to arrest the progress of republican principles, and, fully recognising the inefficiency of the diet, they gave their sanction to the convocation, by a provisional self-constituted assembly, of a national congress of representatives of the people. Archduke John of Austria was elected Vicar of the newly organised national government; but he soon disappointed the hopes of the assembly by his evident attempts to frustrate all energetic action on the side of the parliament, while the speedy success of the anti-republican party in Austria and Prussia damped the hopes of the progressionists. The refusal of the king of Prussia to accept the imperial crown which the parliament offered him, was followed by the election of a provisional regency of the empire; but as nearly half the members had declined taking part in these proceedings, or in a previous measure, by which Austria had been excluded, by a single vote, from the German Confederation, the assembly soon lapsed into a state of anarchy and impotence, which terminated in its dissolution. The sanguinary manner in which insurrectionary movements had, in the meanwhile, been suppressed by Prussian troops both in Prussia and Saxony, put an effectual end to republican demonstrations; and in 1850, Austria and Prussia, after exhibiting mutual jealousy and ill-will, which more than once seemed likely to end in war, combined to restore the diet, whose first acts were the intervention in Slesvig-Holstein in favour of Denmark, and the abolition of the free constitutions of several of the lesser states. Since that period, the diet has been the arena on which Austria and Prussia have striven to secure the supremacy and championship of Germany, and every measure of public interest has been made subservient to the views of one or other of these rival powers. These states did, however, conclude a treaty of alliance in 1854, guaranteeing to each other the mutual defence of their possessions against all enemies—a compact in which the diet soon joined. In 1858, a currency convention was concluded between all the states of the German Confederation, which had previously entered into similar alliances for the adjustment of international postal and commercial relations; and in the same year the diet adopted a resolution by which the Danish government was called upon to submit to the legislative assemblies a new project for the political organisation of the duchies of Holstein, Lauenburg, and Slesvig. In 1859, after many stormy discussions, the assembly passed a resolution to mobilise the whole federal army, and to appoint the Prussian Prince Regent commander-in-chief, subject to the control of the diet, or virtually of Austria, with which rests the casting-vote in the federal assembly. This appointment did not satisfy the ambitious views of Prussia, which has, however, abstained, during the last year or two, from making any very

decisive attempt to secure the supreme political leadership in Germany. A strong anti-Napoleonic feeling has existed since the first outbreak of difficulties between France and Austria; and it may be stated generally, that the discussions and apprehensions to which this sentiment have given rise, together with the consideration of the Slesvig-Holstein difficulties, have constituted the principal questions under discussion in the federal parliament during the sessions of 1859, 1860, and 1861. German Language and Literature.—The numerous dialects which were spoken by the different confederacies and tribes of ancient Germany were all derivatives from one branch of the Aryan or Indo-Germanic family of languages, which separated from the parent stock at a very early period, although subsequently to the separation of the Celtic. We can trace the co-existence of the two branches of Teutonic speech known as Low-German and High-German as far back as the 7th c., but there is no evidence to shew that they existed as common uniform languages, from which their variously modified dialects were respectively derived. According to the eminent philologist Max Müller, there never was one common Teutonic language which diverged into two streams; while the utmost we can venture to assert in regard to the various High and Low German dialects is, that they respectively passed at different times through the same stages of grammatical development. The High-German branch—which was spoken in the dialects of Swabia, Bavaria, and Austria, and parts of Franconia and Saxony—has been the literary language of Germany since the days of Charlemagne. It may be classified under three periods—the Old High-German, dating from the 7th c., and extending to the period of the Crusades, or the 12th c.; the Middle High-German, beginning in the 12th c., and continuing till the Reformation; and the New High-German, dating from Luther's time to our own days. The Low-German, which in Germany itself has been little used in literature, comprehends many dialects, as the Frisian (q. v.), the Flemish, Dutch, Platt-Deutsch, &c. The oldest literary monument of Low-German belongs to the 9th c., and is a Christian epic known as *The Heliand* (the Healer or Saviour); and although there are traces of popular Low-German literature up to the 17th c., the translation of the Bible into High-German by Luther decided the fate of Low-German. In addition to the various dialects which are commonly included under the heads of High and Low German, an important evidence of the cultivation of a form of German differing equally from the High and Low groups has been preserved to us. This important linguistic monument is a fragment of a Gothic translation of the Bible, which was made in the 4th c. by Bishop Ulfilas, and used by all the Gothic tribes when they advanced into Italy and Spain. The Gothic language died out in the 9th c.; and after the extinction of the power of the Goths, the translation of Ulfilas was forgotten and lost sight of till the accidental discovery, in the

16th c., of a MS. preserved in the abbey of Werden, and containing fragments of this important work. This MS. is a copy made in the 5th c. of Ulflas's translation, and fragmentary as it is, it affords evidence of the high degree of development to which this dialect had been carried, and exhibits a form of speech which belongs to neither the High nor Low German group, but very possibly may have been merely one among numerous other allied forms of Teutonic speech which have perished.

The diffusion of Christianity among the Germanic tribes had the effect both of suppressing the use of the Runic characters that had been common to them, and of changing the character of their literature, for instead of the heroic songs and 'beast-epics' of a sanguinary paganism (*Thier-epos*), scriptural paraphrases, legends, and hymns were now selected; while the ancient form of alliteration by degrees gave place to the rhythmical arrangement of the Latin versification common in the early periods of the middle ages. Latin, moreover, became the language of the court, the church, and the law under the Saxon emperors, while German was left entirely to the people, until the new ideas, which were diffused both in regard to literature and language during the Crusades under the rule of the accomplished emperors of the Hohenstaufen line, had the effect of reviving the use and cultivation of the vernacular dialects, among which the Swabian, as the language of the court, soon acquired a marked preponderance over the others. In that age of chivalry and romance, the art of song was cherished by princes and nobles, many of whom belonged to the order of the *Minnesinger* (or Singers of Love), and composed in the Swabian or High-German dialect of the imperial court. The subjects chiefly selected during the 13th and 14th centuries, both by courtly and popular singers, were based on the legendary lore of Charlemagne and his paladins, and King Arthur and his knights, and of the Sangrael; and it is to this period that we must refer the *Nibelungen Lied* and *Gudrun*, which rank as the greatest treasures of German national literature. Among the most successful poets and minnesingers belonging to the Swabian period, we may specially indicate Heinrich von Veldeke, Hartmann von der Aue, Wolfram von Eschenbach, Walther von der Vogelweide, Neidhart of Bavaria, Heinrich von Ofterdingen, &c. The taste for the *Thier-epos* received a new impetus among the people in the middle of the 12th c. by the re-translation, from the Walloon into German, of the ancient poem of *Reinhard Fuchs*, which, according to the distinguished philologist Jakob Grimm, originated with the Frankish tribes, who carried it with them when they crossed the Rhine and founded an empire in Gaul, and from whom it was diffused among the neighbouring tribes of Northern France and Flanders.

The period which succeeded the decline of chivalry was marked by a thorough neglect, among the higher classes, of national literature, which thus fell into the hands of the people, to the thorough disorganisation of all principles of grammar. To this age belongs, however, the great mass of the *Volkslieder*, or national ballads, in which Germany is specially rich; the fables and satires of Brand and of Sachs, and the romances of the satirist Johann Fischart. The mysteries and passion-plays, which were at their height in the 15th c., and still linger in the village of Oberammergau, in Upper Bavaria, may be said to have given origin to the German drama, which numbered among its earliest cultivators, Sachs, Rebhuhn, and Ayser. The close of the 15th c. was prolific in rhyming historical chronicles, in satires on the clergy, and

in theological writings for and against the tottering power of the Romish Church. The writings of Luther, his translation of the Bible, and the works of Ulrich von Hutten, Zuinglius, and of many of the other reformers, were, however, the most important events in the history of German literature from the close of the 15th to the middle of the 16th c.; and it must be remembered that Luther addressed himself to the minds of his countrymen not merely through his polemical writings, but also by those noble hymns, which, since his day, have constituted one of the greatest literary treasures of the kind. Some of the best of these *Kirch-lieder*, or church songs, were composed by Luther himself; while next to him those of Speratus, Decius, Nicolai, and Herberger, have perhaps found most favour both among Germans and foreigners. These fervent effusions of the devout and eloquent reformers were followed by a period of literary degeneration and stagnation, which is in a great measure to be ascribed to the demoralising effects of the Thirty Years' War, when Germany was a prey to all the evils inseparable from civil war fostered by foreign interference. The indirect result of this period of anarchy was to quench the national spirit, and vitiate the popular taste; for while the petty courts aped the habits, language, and literature of Versailles, the lower orders forgot their own literature, with its rich treasures of legends, tales, and ballads, and acquired a taste for the coarse camp-songs imported by foreign mercenaries, and the immoral romances borrowed from impure French and Italian sources. German poetry in the 17th c. was framed after the model of the later classics, and their modern imitators. The study of the genuine national literature was neglected, and although a host of learned societies were formed, whose professed object was to purify and elevate the public taste, the results were lamentably unsatisfactory; and it was not till J. C. Gottsched (1700—1766) succeeded in his *Critical Art of Poetry* in drawing attention to the turgid pedantry and artificial stiffness of the classicist school, that a better taste was awakened. His own pretentious bigotry gave origin, however, to a counter-party, from which emanated, at a somewhat later period, the German æsthetic school, under the guidance of A. Baumgarten and G. Meier. A favourable reaction now took place, and with the names of Klopstock, Lessing, and Wieland began the brilliant epoch of modern German literature. Their influence was alike great and varied; for while Klopstock's poem of the *Messiah*, and his odes, in which he had taken Milton as his model, re-echoed the tender piety of the old reformers, and were so thoroughly German in their spirit, that they at once met with an enthusiastic response in the hearts of the people, Lessing's tragedy of *Minna v. Barnhelm*, and his drama of *Nathan der Weise*, may be said to have created anew the dramatic art in Germany. Wieland, on the other hand, who was the complete antithesis of Klopstock, although, like his two great contemporaries, he was the founder of a new style, and gave a graceful flexibility to German diction, which it had never before been made to assume, had imparted to his numerous tales and romances an undisguised sensuous materialism, which, like his style, had been borrowed from the French philosophers of his day, and thus introduced into the language and literature of Germany the germs of many defects, as well as graces, to which they had hitherto remained strangers. The influence exerted on German literature by these three writers, who may be regarded as its regenerators, was soon appreciable in every branch of knowledge; and among the galaxy of great names which have

imparted renown to the literary and scientific annals of Germany during the last 100 years, we can only instance a few of the principal writers who have more especially enriched the several departments of learning with which they have been associated.

Philosophy, which in Germany originated with Leibnitz, who, however, wrote in Latin and French, assumed a degree of individuality and completeness through the intellectual acumen and subtle analysis of Kant, Fichte, Schelling, and Hegel, which have no parallel in any other country. In theology, Reinhard, Paulus, Schleiermacher, and a host of others, have infused new life into biblical inquiry; while invaluable aid has been afforded in the same direction by the profound philological and critical researches of Wolf, Hermann, Müller, the erudite brothers J. and W. Grimm, Bopp, Benecke, Adelung, Lassen, Rosen, Schlegel, W. Humboldt, Lepsius, Bunsen, &c. In archaeology, history, and jurisprudence, all nations owe a debt of gratitude to Winckelmann, Heeren, Von Raumer, Schlosser, Von Hammer, Gervinus, Dahlmann, Ranke, Niebuhr, and Mommsen. In poetry and belles-lettres, the name of Goethe (who lived from 1749 to 1832) is a host in itself. He had been preceded in the school to which he attached himself, which was known as that of the *Sturm- und- Drang* period, by Herder, its originator, whose philosophical critiques of foreign and German literature, by reviving a taste for the long-forgotten national poetry of Germany, and by exhibiting the weakness of the recent imitations of the French classicists, contributed materially to the complete literary revolution which ushered in the modern period of German poetry. In his *Leiden des Jungen Werther* (The Sorrows of Werther), Goethe carried the sentimental tendencies of the school to their culminating point; but while he was followed in the same path by a host of imitators, who brought the style into ridicule by their morbid exaggerations, his own later and very numerous works became in time more and more free from the blemishes into which he had led others, and remain imperishable monuments of the universality of his genius. The *Sturm- und- Drang* period closed with Schiller (1759—1805), who ranks in the estimation of his countrymen almost as high as Goethe himself, and whose early works, *The Robbers*, *Fiesco*, and *Don Carlos*, threw the whole German people into a frenzy of excitement. His later dramatic works, if less exciting than these, gave evidence of more matured taste, while some of his ballads and lyrics may be said to be unrivalled. In the present century, poetry has found noble representatives in the so-called *Vaterlandsdichter* (Poets of the Fatherland), among whom we may instance Theodor Körner, and Arndt, whose spirited patriotic songs are intimately associated with the war of 1813 against Napoleon, in which the former fell fighting gloriously. F. Rückert and L. Uhland belong to the same school; but the former is more especially known for his admirable adaptations and translations from the Oriental languages, and the latter for his exquisite romances and ballads. The influence of Goethe and Schiller extended in a marked degree to the drama and to novel-writing. In the former department, Iffland acquired great reputation as a writer of sensation dramas, A. von Kotzebue as an inexhaustible composer of light effective comedies, A. Müllner v. Honwald, F. Grillparzer, and E. Raupach for their historical and social tragedies, while C. Immermann (who is better known as the author of the novel *Münchhausen*), Moesen, Laube, and G. Freytag, have all produced good dramatic pieces. Among the host of novelists who have endeavoured to follow in the steps of the great leaders of the *Sturm- und- Drang*

period, the majority are unworthy of notice. J. P. Richter, the satirist and humorist, stands forth, however, apart from, and far above his contemporaries; and few novelists ever exerted so lasting an influence on the literature and mode of feeling of their compatriots as that which Richter exercised over the minds of the middle classes of Germany, during the close of the last and the early part of the present century. Among other writers of note, we may instance De la Motte Fouqué, A. Hoffmann, and A. Chamisso, whose tendencies were to dwell on the mysterious agencies of nature, which they attempted to individualise, and bring into association with material forms, as in the *Undine* of the first, the fantastic tales of the second, and the *Peter Schlemihl* of the last-named. C. Fichler, Spindler, H. Steffens, C. Gutzkow, Sternberg, W. Häring (the imitator of Sir W. Scott), Hauff, Zachokke, an admirable writer of *novellettes*, Hackländer, Ida v. Hahn-Hahn, Auerbach, the narrator of village tales, and Freytag, the author of a social novel, *Soll und Haben*, have all in turn enjoyed universal popularity.

But numerous as have been writers of poetic and dramatic literature during the present century in Germany, the tendency of the German mind has of late years been rather to science than fiction; and the immense impetus given to the taste for scientific inquiry by A. v. Humboldt's travels and observations, and by his *Cosmos* and *Views of Nature*, has been followed by the prosecution of the most profound researches in every department of physical and natural science, and by the appearance of a multitude of records of travel, among the more important of which we can only instance a few, as, for example, those of Martius in Brazil, Pöppig in S. America, Tschudi in Peru, Schubert in Greece, Lepsius and Brugsch in Egypt, Schomburgk in British Guiana, Gützlaff in China, Siebold in Japan, the three brothers Schlagentweit in the Alps and in Central Asia, Barth and Vogel in Africa, and Leichhardt in Australia. In conclusion, we can only group together the names of a few of the many eminent Germans who by their labours have at once enriched the science of the world, and enhanced the literary and scientific glory of their own country. Without again referring to writers whom we may already have mentioned, we may specially instance, in astronomy and mathematics, Bessel, Encke, Struve, Gauss, and Mädler; in the natural sciences, and in medicine, J. Müller, Ehrenberg, Carnus, Oken, Schleiden, Von Buch, Liebig, Kopp, Simon Dova, Valentin Moleschott, Bischoff, Rose, Poggendorf, Erdmann, Gmelin, Gräfe, Vogel, Rokitanaky, Wagner, Schönlein, and Dieffenbach; in history and biography, Niebuhr, Leo, Duncker, Preuss, Böttiger, Varnhagen v. Ense, Pertz, Lappenberg, Pauli, &c.; in geography, ethnology, statistics, and travels, Berghaus, Petermann, Stein, Hübnér, Klöden, Kohl, Reinbeck, Bunsen, Ideler, Lassen, Unger, Zimmermann; in the history of language, literature, and the fine arts, and on politics and the social sciences, Vilmar, Bouterwek, Kuno, Fischer, Waagen, Heinsius, Heyse, Becker, Creuzer, Lersch, Wachler, Ernesti, Jacobs, Savigny, Eichhorn, Bülow, Ersch. See Grimm, *Geschichte d. Deutschen Sprache*, and *Deutsche Grammatik*; Bopp, *Comparative Grammar*; Bessel, *Ueber das Leben des Uffia*; M. Müller, *On the Science of Language*; Koberstein, *Grundriss der Deutschen Nationalliteratur*; Vilmar, *Vorlesungen über die Geschichte d. Deutsche Nationalliteratur*; Hallam, *Europe in the Middle Ages*.

GERMEN (Lat. a sprout), or O'VARY, the lowest and thickened part of the Pistil (q. v.) of a flower; containing in its cavity the rudiments of the seeds, called Ovules (q. v.), attached to the Placenta

(q. v.) often by *umbilical cords* (q. v.). There is often only one ovule in the germen; sometimes it consists of a number of *Carpels* (q. v.), with one ovule in each; occasionally the cavity of the germen is divided into cells, each of these containing one, and often many ovules. When there are many ovules, some of them are generally abortive. The germen is sometimes *superior*—that is, it is *free* in the centre of the flower, as in the poppy, stock, and carnation; occasionally *inferior*, the calyx being adherent to it throughout, and the upper part or limb of the calyx thus seeming to arise from its summit, as in the gooseberry, rose, campanula, and snowdrop; sometimes it is half inferior, as in *Saxifraga granulata*. The germen develops itself into the *Fruit* (q. v.), after the flowering is over. Some plants bend their flower-stalks to the ground after flowering, press the germen into the ground, and ripen their fruit in the earth, as a species of Clover (*Trifolium subterraneum*), and the Ground-nut (*Arachis hypogaea*). See ARACHIS.

GERMINATION (Lat. sprouting), the beginning of growth in a seed, or of the vital action by which it is converted into a new plant. See SEED; and for what is peculiar to acotyledonous plants, see SPORE.

GERONA (anc. *Gerunda*), a city of Spain, in lat. 41° 58' N., long. 2° 50' E., capital of the province of the same name, is situated at the confluence of the Ter, with its affluent the Onar, 60 miles north-east of Barcelona. It consists of an old and new town, the latter irregularly built on the declivity of a rocky hill, but highly picturesque, and containing a beautiful and lofty Gothic cathedral, commenced in 1316, and approached by a superb flight of steps. Besides the cathedral, there are five churches and twelve convents. The inhabitants carry on the manufacture of paper, soap, and leather; and spinning and weaving. The city is fortified by high thick walls, and protected by four forts. Pop. 13,959.

G. was of Roman origin, and was formerly the residence of the kings of Aragon. It has suffered much from sieges, of which the most noteworthy was that of 1809, when the French with 35,000 men encompassed and assailed the town. The besieged, unprovided with everything, even with ammunition, maintained a defence for seven months and five days against seven open breaches, and were forced to capitulate only when their heroic governor was struck down by famine and disease.

GEROPIGIA, or JERUPIGIA. Of late years, a considerable quantity of this material has been sent from Portugal to this country. It consists of grape juice unfermented, and colouring matter, probably the extracts of rhatany-root and logwood, with sufficient brandy and sugar to preserve it from fermentation. It is used for giving a spurious strength and colour to red wines, more especially to those intended for exportation—the factitious compound being mixed or vatted with the wines in bond. At least 20,000 gallons are now imported annually, and this large trade has sprung up within the last fifteen years.

GERSE, a department in the south-west of France, is formed of portions of the old provinces of Gascony and Guienne. The department of Landes intervenes between it and the Bay of Biscay, and that of Hautes-Pyrénées between it and the frontiers of Spain. It has an area of 2403 square miles, and a pop. of 304,497. The surface toward the south is mountainous, covered with ramifications of the Pyrenees, which extend northward in parallel lines. These lines decrease

in height as they advance, and are separated by fan-shaped valleys, which are only a few yards wide in the south, but expand to a width of several miles in the north of the department. The principal rivers are the Gers—which gives its name to the department—the Lousse, the Baise, the Arratz, the Gimone, and the Save. The climate is healthy and temperate. The soil is a stiff loam, resting on thick layers of clay, and is only moderately productive. More than one-half of the surface is devoted to agriculture, one-seventh is in vineyards, and the rest in meadows, heaths, and forests. Wine is produced in considerable quantity, but of an inferior quality; great part of it is converted into Armagnac brandy, which, after Cognac, is esteemed the best. The manufactures and exports are inconsiderable. The town of Auch is the capital.

GERSON, JEAN DE, one of the most eminent scholars and divines of the 14th and 15th centuries. His proper name was Jean Charlier, the name of G. being given to him from the place of his birth (1363), the village of Gerson in the diocese of Rheims. He was educated in the university of Paris, under the celebrated Peter d'Ailly. Here he rose to the highest honours of the university, and ultimately to its chancellorship, having acquired by his extraordinary learning the title of 'The Most Christian Doctor.' During the unhappy contests which arose out of the rival claims of the two lines of pontiffs in the time of the Western Schism, the university of Paris took a leading part in the negotiations for union; and G. was one of the most active supporters of the proposal of that university for putting an end to the schism by the resignation of both the contending parties. With this view, he visited the other universities, in order to obtain their assent to the plan proposed by that of Paris. But although he had the satisfaction to see this plan carried out in the council of Pisa, it failed, as is well known, to secure the desired union. In a treatise inscribed to his friend D'Ailly, he renewed the proposal that the rival pontiffs (now not two, but three since the election of John XXIII. at Pisa) should be required to resign; and in the new council held at Constance in 1414, he was again the most zealous advocate of the same expedient of resignation. It is to him, also, that the great outlines of the plan of church reformation, then and afterwards proposed, are due. But his own personal fortunes were marred by the animosity of the Duke of Burgundy and his adherents, to whom G. had become obnoxious, and from whom he had already suffered much persecution, on account of the boldness with which he had denounced the murder of the Duke of Orleans. To escape their vengeance, he was forced to remain in exile; and he retired from Constance, in the disguise of a pilgrim, to Rattenberg in Bavaria, where he composed his celebrated work *De Consolatione Theologia*, in imitation of that of Boethius, *De Consolatione Philosophiæ*. It was only after the lapse of several years that he was enabled to return to France, and take up his residence in a monastery at Lyon, of which his brother was the superior. He devoted himself in this retirement to works of piety, to study, and to the education of youth. He died in 1429, in his 66th year. His works, which are among the most remarkable of that age, fill five volumes in folio. Among the books formerly ascribed to him was the celebrated spiritual treatise *On the Imitation of Christ*; but it is no longer doubtful that the true author is Thomas-a-Kempis. See KEMPIS. The authority of G. is much relied on by the advocates of Gallican principles; but the Ultramontanes allege that the principles laid down by him as

to the authority of the pope are only applicable to the exceptional case in which he wrote—viz., that of a disputed succession, in which the claim of each of the rival popes, and therefore of the existing papacy itself, was doubtful.

GERSTÄCKER, FRIEDRICH, a German novelist and traveller, was born at Hamburg, 16th May 1816. In 1837, he went to America. After spending some months in New York, he began his wanderings through the United States, sometimes as a stoker or sailor in various steam-packets, sometimes as a silversmith, a woodcutter, a maker of pill-boxes, &c., working till he had earned money enough to enable him to proceed further. He also led for a considerable period a wild adventurous life as a hunter in the forests. In 1842, he set up a hotel at Point Coupée, in Louisiana; but in 1843, a strong desire to see his friends induced him to return to Germany. Here he published his admirable *Streif- und Jagdtage durch die Vereinigten Staaten Nordamerikas* (2 vols., Dresden, 1844). This was followed by his *Die Regulatoren in Arkansas* (3 vols., Leip. 1846), *Die Flusspiraten des Mississippi* (3 vols., Leip. 1848), *Mississippibilder, Licht- und Schattenseiten transatlantischen Lebens* (2 vols., Dresden, 1847), *Amerik. Wald- und Strombilder* (2 vols., Leip. 1849). In his popular writings, as the *Reisen um die Welt* (6 vols., Leip. 1847), and *Der Deutschen Auswanderer Fahrten und Schicksale* (Leip. 1847), G. contrives to rivet the attention even of the uneducated reader. In 1849, G. again set out on his travels, and went from Rio Janeiro by Buenos Ayres to Valparaiso and California, whence he proceeded to the Sandwich Isles, crossed in a whaling-vessel to the Society Islands, went on to Sydney, travelled through Australia, and returned to Germany in 1852, where he has since resided. His contributions to the *Ausland* and *Allgemeine Zeitung*, containing an account of his recent travels, were collected and published under the title of *Reisen* (1853—1855). His works have been partly translated into French and English.

GERUND (from Latin *gero*, I carry on) is a part of the Latin verb which, according to grammarians, declares that anything is to be done. Thus the gerund of *scribo*, I write, is *scribendum*; as, *charta utilis ad scribendum*, paper useful for writing. It is a sort of verbal noun, possessing the same power of government as its verb, but is scarcely ever found in the nominative, at least as a governing word. In French, the infinitive has almost entirely supplanted the gerund, the sole surviving remnant, we believe, being found after the preposition *en*, as *en attendant*. In English, the present participle does duty also for the gerund; as, he is reading novels (participle); he amuses himself with reading novels (gerund).

GERVAS (*Stachytarpheta Jamaicensis*), a small shrub of the natural order *Verbenaceae*, a native of the West Indies and warm parts of America. It has scattered hairy branches, oblong-ovate coarsely and sharply serrated leaves about two inches long, and long dense spikes of lilac flowers. It is regarded as a stimulant, febrifuge, anthelmintic, and vulnerary; a decoction of the leaves is applied to severe contusions; and the dried leaves are used as tea. In Austria, they are sold under the name of *Brazilian Tea*. In Britain, they are employed only for the adulteration of tea; but for this purpose they are perhaps more frequently used than any other kind of leaf.

GERVASE OF TILBURY, an historian of the 13th c., was born at Tilbury, in Essex. He is said to have been a nephew of King Henry II. of England. About 1208, he was received with great distinction

at the court of Otho IV., emperor of Germany, and appointed by that monarch marshal of the kingdom of Arles. He died about 1218. He wrote a commentary upon Geoffrey of Monmouth's History of Britain, entitled *Illustrationes Galfridi Monemuthensis*, lib. iv.; a History of the Holy Land (*Historia Terra Sanctae*); a treatise, *De Origine Burgundionum*; and a History of the Kings of England and France, comprised in a work entitled *Otha Imperialia*, libri tres; also known under the titles, *Mappa sive Descriptio Mundi*, and *De Mirabilibus Orbis*. MSS. of the *Otha Imperialia* are preserved in the Cottonian Collection, and in the library of Corpus Christi, Cambridge. Nicolson ascribes to G. the Black Book of the Exchequer (*Liber Niger Scaccarii*). Madox, who published a very correct edition of that work, makes Richard Nelson, Bishop of London, the author.

GERVINUS, GEORG GOTTFRIED, an historian of German literature and politician, was born at Darmstadt, 20th May 1805. He received a mercantile education, and was for some time employed in the counting-house of a merchant in his native town. By a diligent course of self-instruction, he supplied what was wanting in his school-education, and in 1826, was so far advanced as to be ready to enter the university of Heidelberg. After completing his studies, during which a taste for history had been awakened in him by Schlosser's lectures, he became teacher in an educational institution at Frankfurt-on-the-Maine. In 1835, he was appointed a professor extraordinary at Heidelberg. Previous to this, he had published his *Geschichte der Angelsachsen im Ueberblick* (Frank. 1830), which was followed by his *Historische Schriften* (Frank. 1833). In 1836, he was appointed ordinary professor of history and literature at Göttingen. He had now begun to publish his *Geschichte der Poetischen Nationalliteratur der Deutschen* (3 vols., Leip. 1835—1838; 3d edit. 1846—1848). This was followed by the *Neuere Geschichte der Poetischen Nationalliteratur der Deutschen* (2 vols., Leip. 1840—1842; 3d edit. 1852). Both of these works have attained to well-deserved popularity. In 1837, he was one of the Göttingen professors who signed the famous protest against the abolition of the Hanoverian constitution, in consequence of which he lost his chair, and was ordered to leave the country within three days. He first went to Darmstadt, then to Heidelberg, and in the spring of 1838, to Italy. He spent the winter in Rome, engaged in historical studies. In 1844, he was appointed honorary professor in the university of Heidelberg. From this period, his career was that of a political writer. Constitutional liberty was the object which he had in view, and for which he ardently laboured. His pamphlets and writings in different periodicals exercised a very great influence over the national mind. In July 1847, along with some others, he established the *Deutsche Zeitung* in Heidelberg, to advocate the political views of the Constitutionalists. In 1848, he was deputed to attend the diet in behalf of the Hanne towns, and was elected a member of the National Assembly by a district of Prussian Saxony. After the failure of the national democratic party in Germany, G. returned to his literary pursuits, the fruits of which are his able and suggestive work on Shakspeare (4 vols., Leip. 1849—1850), his *Geschichte der Deutschen Dichtung* (5 vols., Leip. 1853), and his *Geschichte des neunzehnten Jahrhunderts* (Leip. 1st vol., 1853; 3d vol., 1858; English translation, 1859).

GESENIUS, FRIEDRICH HEINRICH WILHELM, one of the greatest modern German Orientalists and biblical scholars, was born at Nordhausen, in Prussian Saxony, 3d February 1785, and educated

first at the gymnasium of his native town, afterwards at the universities of Helmstedt and Göttingen. After having been a short time teacher in the pædagogium at Helmstedt, he became in 1806 a theological *Repetent* in Göttingen; and in 1809, on the proposal of Johann von Müller, was appointed professor of ancient literature in the gymnasium of Heiligenstadt. In 1810, however, he received a call to Halle as extraordinary professor of theology, and was made an ordinary professor in the following year. In 1810—1812, he published, in two volumes, a *Hebrew and Chaldean Dictionary of the Old Testament*, which underwent improvements in several subsequent editions, after he had made a journey to Paris and Oxford in the summer of 1820, to make researches in the Semitic languages. In the two years following the publication of this Dictionary, appeared his *Hebräisches Elementarbuch* (2 Bde., Halle, 1813—1814), consisting of a Hebrew grammar and reading-book. This work, as it has been improved in the recent editions of G.'s distinguished pupil and literary executor, Professor Rödiger of Halle, and the lexicon already mentioned, are still the grammar and dictionary of the Old Testament most in use not only throughout Germany, but in Great Britain and in America. The best English translations of the dictionary founded on the Latin edition are those of Robinson (American), and of Tregelles; the best of the grammar are those of Davies (London) and of Conant (New York). In 1815, another work was published by G. on the history of the Hebrew language (*Kritische Gesch. d. Hebr. Sprache u. Schrift*, Leip.), and a treatise, *De Pentateuchi Samaritani Origine, indole et auctoritate* (Halle). Besides a translation of Isaiah with a commentary in three vols. (Leip. 1820—1821), we are indebted to G. for a larger Hebrew Grammar (*Grammatisch-kritisches Lehrgebäude d. Hebr. Sprache*, 2 Bde., Leip. 1817), as well as for a larger lexicographical work (*Thesaurus philologico-criticus Lingue Hebraicæ et Chaldaicæ Veteris Testamenti*), of which the first part was published in 1829, but which was completed only in 1858 by Professor Rödiger. G. contributed also some papers on Oriental Antiquity to Ersch and Gruber's *Allgemeine Encyclopædie*; and his notes to the German translation of Burckhardt's *Travels in Syria and Palestine*, throw light on many points connected with biblical geography. He died 23d October 1842, and a memorial of him appeared in the following year (G., *eine Erinnerung an seine Freunde*, Berlin, 1843).—Many of the results of the rationalising method of interpreting the Old Testament, which characterises all the works of G., have been unable to stand the progress of biblical science, and he has certainly been surpassed by Ewald in insight into the genius of the Hebrew language, and its bearing on the interpretation of Hebrew life and thought, as well as in all that qualifies the critic for a true historical, æsthetic, and religious appreciation of the literature preserved to us in the Old Testament. Yet his intense devotion to his favourite studies, and the advance which he made beyond all his predecessors in the establishment of more certain principles of Hebrew philology, undoubtedly entitle him to be regarded as having constituted a new epoch in the scientific study of the Old Testament.

GESNER, KONRAD VON, a celebrated Swiss naturalist, was born at Zürich in 1516, and died there of the plague 13th December 1565. His father, who was a leather-seller, was too poor to pay for more than the first years of his education at the town-school; but John Jacob Ammanius, professor of Latin and oratory in the college, saw in the boy so much promise, that he took him

into his house, and instructed him gratuitously for three years in Latin, Greek, dialectics, and oratory. He subsequently studied for three or four years at Paris, whence he was summoned back to Zürich, to become a teacher in the school in which he had derived the elements of his own education. He devoted all his spare time to the study of medicine and botany, in the hope of ultimately rising from the office of a schoolmaster to that of a professor. The hope was gratified upon the opening of the university of Lausanne, when he was appointed professor of Greek. After holding the office three years, he went to Montpellier, where he attended medical lectures, and to Basel, where, after additional study, and the usual disputations, he was admitted to the degree of Doctor of Medicine. He then, at the age of twenty-five years, returned to his native town. In a very short time, he received the appointment of professor of philosophy, which he held until his death. He likewise practised medicine, and published from time to time the fruit of his studies. As, in the course of his life, he published no less than seventy-two works, besides leaving at his death eighteen that were in progress, it will be impossible for us to notice more than a few of the most important. His first great work, the *Bibliotheca Universalis*, appeared when he was only twenty-nine years old. It contained the titles of all the books then known in Hebrew, Greek, and Latin, with criticisms and summaries of each; and as an index to authors who wrote before the year 1545, it remains to this day very valuable. Ten years later (in 1555), his *Mithridates, de Differentiis Linguarum* appeared, which contained histories of one-hundred-and-thirty ancient and modern languages. But by far the greatest of his literary works was his *Historia Animalium*, which was planned in six books, of which only four were completed. The first treats of viviparous, and the second of oviparous quadrupeds (tortoises, lizards, &c.), the third of birds, and the fourth of fishes and aquatic animals. The fifth book was to have contained the history of serpents, and the sixth that of insects. Each of the four published books is a folio of considerable thickness, and with closely printed pages. In this work, which will ever remain a monument of his untiring industry, he aimed at bringing together all that was known in his time concerning every animal. The information which he collected regarding each animal was arranged under eight heads, represented by the first eight letters of the alphabet. These four volumes contain the complete history, up to the middle of the sixteenth century, of beasts, birds, and fishes, and well entitle their author to the designation which he often received of 'the German Pliny.'

Botany was probably the section of natural history with which he had the greatest practical acquaintance. He had collected more than five hundred plants undescribed by the ancients, and was arranging the results of his labours in this department at the time of his death. He appears to have been the first who made the great step towards a scientific classification of distinguishing genera by a study of the fructification.

GESNERACEÆ, a natural order of exogenous plants, allied to *Scrophulariaceæ*, and consisting of herbaceous plants and soft-wooded shrubs, generally tropical or sub-tropical. They frequently spring from scaly tubers. The leaves are wrinkled and destitute of stipules. The calyx is 5-parted; the corolla, tubular, 5-lobed, more or less irregular. The stamens are generally four, two long and two short, with the rudiment of a fifth. The germen is half inferior, surrounded at its base by glands or a fleshy ring; it is one-celled, and has parietal placentæ.

The fruit is either a capsule or a berry, many-seeded. — There are about 120 species, exclusive of those sometimes formed into a distinct order under the name *Cyrtandraceae* or *Didymocarpeae*, of which there are about 140. The true *Gesneraceae* are all natives of the warmer parts of America, where some of them grow upon trees. The *Cyrtandraceae* are more widely distributed. — Some plants of this order have mucilaginous and sweetish edible fruits; but it is chiefly remarkable for beauty of flowers, containing some of the most admired ornaments of our hothouses, as species of *Gloxinia*, *Achimenes*, &c.

GESSLER, ALBRECHT, called also G. von Bruneck, was in 1300 appointed joint-governor along with Berenger von Landenberg, of the Waldstättlen or Forest Cantons (Schwytz, Unterwalden, and Uri), by Albrecht I. of Austria. According to the traditions connected with Tell (q. v.), his oppressive edicts and wanton cruelty so enraged the inhabitants that a conspiracy was formed against him, and he was shot by Tell in a narrow pass near Küssnacht in 1307.

GESSNER, SALOMON, a German poet and artist, was born at Zürich, 1st April 1730, and apprenticed to a bookseller in Berlin in 1749, but soon ran away from his master, and endeavoured to earn a livelihood by landscape painting. From Berlin he went to Hamburg, where he formed an intimate friendship with Hagedorn. On his return to Zürich, he published *Daphnis*, which was followed by *Inkle und Yarico*, a small volume of idylls, and *Tod Abels* (the Death of Abel), a species of idyllic heroic prose poem, which, though the feeblest of all his productions, is the best known, and the one on which his claim to the notice of posterity rests. He afterwards turned his attention for several years exclusively to painting and engraving, in the latter of which arts he attained high excellence. Some of the engravings with which he illustrated his feeble poetry are said to be worthy of the first masters. In 1772, he published a second volume of idylls, and a series of letters on landscape painting. He died 2d March 1787.

GESTA ROMANORUM is the title of the oldest legendary work of the middle ages. The stories are written in Latin, and for the most part are either taken from the histories of the Roman emperors, or at least are referred to the period in which these flourished. At a later period, moralising expositions were added, whence the work obtained the name of *Historia Moralizata*. The G. R. belongs to that class of works with which the monks were wont to beguile their leisure hours, and which were appointed to be read in the refectory. The stories are short, and destitute of rhetorical ornament; neither have they any dialogues or tragic incidents. Their attractiveness lies in the charm of their naïveté and childlike simplicity, although their artless piety often passes into a deep mysticism. Down to the 16th c., the G. R. was one of the most widely read books among the learned, as the number of manuscripts and of printed impressions shortly after the invention of printing (the first was issued at Cologne in 1472) prove. At an early period, it was translated into French, English, German, and Dutch. The oldest Dutch translation was published at Gouda by Gerard Leeu in 1481; the oldest German translation at Augsburg, by Hans Schobser, in 1489. Among the older English translations may be mentioned that by R. Robinson (Lond. 1577). Recently (1824), the Rev. C. Swan published *Gesta Romanorum, translated from the Latin, with Preliminary Observations, and Copious*

Notes. The later German fabulists and novelists, such as Hans Sachs, Burkard Waldis, and others, made abundant use of this great storehouse. But soon after the Reformation it was thrown into the background, and even in the monasteries, where for a long time it maintained its footing, it was at length forgotten. Recently, however, amid the general revival of interest in the literature of the past, it has received special attention. Its author has been supposed by some to have been Petrus Berchorius or Bercheur of Poitou, who died prior of the Benedictine Abbey of St Eloi in Paris in 1362, but it is now believed that he only added the moralisings; and Grässe, in an appendix to his German translation (2 vols. Dresd. and Leip. 1842), has shewn that a certain Elinandus is the author or compiler of the work. This Elinandus was undoubtedly a monk, and was either an Englishman or German, as is clear from the numerous Germanisms and Anglicisms that pervade the *Gesta*. The most recent edition of the original text is that of Keller (Stutt. and Tüb. 1842).

GESTATION, in Physiology, is the term applied to the period that intervenes in the mammalia between impregnation and the bringing forth of the young. The period and the number of young produced at a birth vary extremely in different mammals, but usually stand in an inverse ratio to one another. Thus, in the larger herbivora, as, for example, the elephant, the horse, the ox, and the camel, the female seldom produces more than one at a time, but the period of gestation is long; while in the smaller ones the progeny is numerous, but the period of gestation only a few weeks. In the elephant, the period of gestation extends over twenty or twenty-one months; in the giraffe, it is fourteen months; in the dromedary, it is twelve months; in the mare, upwards of eleven months; in the tapir, between ten and eleven; in the cow, nine; and in many of the larger deer somewhat more than eight months. In the sheep and goat, the period is five months. In the sow, which produces a numerous litter, the period is four months. In the rodentia, the progeny is numerous and imperfectly developed, and the period of gestation is comparatively short: in the beaver, one of the largest of the order, it is four months; in the rabbit and hare, from thirty to forty days; in the dormouse, thirty-one days; in the squirrel and rat, four weeks; and in the guinea-pig, three weeks or less. The young of the carnivora, like the young of the rodentia, are born with their eyes closed, and in a very immature condition; and in even the larger carnivora the period of gestation is far shorter than in the larger ruminantia or pachydermata: it is six months in the bear; one hundred and eight days in the lion (the period in this animal is stated by Van der Hoeven at three months); seventy-nine days in the puma; sixty-two or sixty-three days in the dog, the wolf, and the fox; and fifty-five or fifty-six days in the cat. In the marsupial animals, which, from a structural peculiarity, produce their young in a far more immature state than any other mammals, the period of gestation is very short, being thirty-nine days in the kangaroo, the largest of the marsupial animals, and only twenty-six days in the opossum. Nothing certain is known regarding the period of gestation of the cetacea. The quadrumana produce one, sometimes two, at a birth; and the period of gestation, as far as has been observed, seems to be seven months. In the human race, forty weeks is the usual period of gestation, but this period is liable to certain deviations, which are noticed in the article *FÆTUS*.

GETÆ, a people of Thracian extraction, who, when first mentioned in history, inhabited the

country which is now called Bulgaria. They were a warlike people, and for a long time successfully resisted the attempts of Alexander the Great and Pyrrhus to subdue them. They afterwards removed to the north bank of the Danube, having the Dnieper as their boundary on the east, while westward they encroached on the Roman empire, with which from this time they were continually at war. They were called Daci by the Romans, and their country Dacia, and are often mentioned in the literature of the Augustan era as savage and unconquerable foes. During the reign of Domitian, they overcame the Romans, and exacted an annual tribute. But in 106, their gallant king, Decebalus, was defeated by Trajan, and the people completely subdued. A Roman colony was settled in the country, and becoming incorporated with the G., gave rise to a mixed race, the modern Wallachs.

GETHESEMANE (Heb. *Geth*, 'a wine-press,' and *Shemen*, 'oil'), the scene of our Saviour's agony on the night before his Passion, was a small farm or estate at the foot of Mount Olivet, and rather more than half a mile from the city of Jerusalem. Attached to it was a garden or orchard, a favourite resort of Christ and his disciples. The spot pointed out to modern travellers as the site of the garden of G. corresponds sufficiently with the requirements of the Scripture narrative, and the statements of Jerome and Eusebius. It is a place about 50 paces square, enclosed by a low wall of loose stones, and contains eight very old olive-trees, regarded with pious superstition as having existed in the time of our Lord.

GE'UM, a genus of plants of the natural order *Rosaceæ*, sub-order *Potentilleæ*, nearly allied to *Potentilla*, but distinguished by the hardened hooked styles which crown the carpels, so that the fruit becomes a bur. The carpels are dry. Two species are common natives of Britain, *G. urbanum*, called COMMON AVENS, or HERB BENNETT, a herbaceous plant, about 1-2 feet high, and *G. rivale*, called

meadows and woods, and sometimes even in very alpine situations. Both are aromatic, tonic, and astringent, and are employed to restrain mucous discharges, and in cases of dysentery and intermittent fever. The root of *G. rivale* is also used in diseases of the bladder. The root of *G. urbanum*, when fresh, has a clove-like flavour, which it communicates to ale; and for this purpose it is gathered in spring before the stem grows up. *G. Canadense*, the CHOCOLATE ROOT or BLOOD ROOT of North America, has some reputation as a mild tonic. It is much employed in the United States in diseases of the bladder. It much resembles the British species in its leaves, and has erect flowers like *G. urbanum*. A number of other species are known, natives of the temperate and colder regions both of the northern and southern hemispheres.

GEYSER (Icelandic, *geysa*, to burst forth violently, allied to Eng. *gush*) is a term applied in Iceland to the eruptive thermal springs and wells which are found in various parts of its surface in evident connection with the volcanic forces at work below. The most remarkable group of these singular objects is one about 70 miles, or a two days' ride from Reikiavik, 16 miles north of Skalholt, and within sight of the volcano of Hecla. On the slope of a low trap-hill, overlooking the wide grassy valley of the Whitae, or White River, a space of ground measuring perhaps half a mile each way is thickly interspersed with boiling or hot springs, of various sizes, from jets not greater than an overboiling tea-kettle, up to great caldrons, besides vestiges of others no longer in operation. All are surrounded by silicious incrustations, formed in the course of time by the minute charge of silica infused into the water. The chief apertures are two, respectively called the Great Geyser and the Strokr (i. e. Churn), which are little more than a hundred yards apart. The latter is an irregular aperture of from six to eight feet diameter, down which one may in general safely look, when he sees the water noisily working in a narrower passage about 20 feet below. If, by throwing in a sufficient quantity of turf, he can temporarily choke this gullet, the water will in a few minutes overcome the resistance, and, so to speak, perform an eruption with magnificent effect, bursting up 60 feet into the air, brown with the turf that has been infused into it, and diffusing steam in vast volumes around.

The appearance of the Great Geyser is considerably different. On the summit of a mount which rises about 15 feet above the surrounding ground, is a circular pool or cup of hot water, 72 feet across at its greatest diameter, and about four feet deep, being entirely formed of silicious crust of a dull gray colour. At the edge, this water has been found to be 188° F.; in the centre, it is considerably higher. From the centre descends a pit of eight feet width, and 83 feet deep, up which a stream of highly heated water is continually but slowly ascending, the surplus finding its way out by a small channel in the edge of the cup, and trickling down the exterior of the crusty eminence. Every few hours, the water, with a rumbling noise, rises tumultuously through the pit, and jets for a few feet above the surface of the pool; by and by, it subsides, and all is quiet again. Once a day, however, or thereabouts, this tumult ends in a terrific paroxysm, which lasts perhaps a quarter of an hour, and during which the water is thrown in repeated jets from 60 to 80 feet high, mingled with such volumes of steam as obscure the country for half a mile round. If a visitor be tolerably near on the windward-side, he may catch glimpses of this grand spectacle—the eruption of a

Geum Rivale :

a, carpel and awn, b, petal, c, stamen; d, pistil.

WATER AVENS, about one foot high, both of which have the radical leaves interruptedly pinnate and lyrate, and the cauline leaves ternate, but *G. urbanum* has erect yellow flowers, and *G. rivale* has nodding flowers of a brownish hue. The former grows in hedges and thickets, the latter in wet

water-volcano, it may be termed—and he must needs be charmed with the beautiful jets as they curve outwards and fall, as well as impressed by the sublimity of the whole scene. When quiet is restored, the chalice, and perhaps twenty feet of the pit, are found empty, and the visitor obtains, so far, a sight of the internal arrangements and structure of the geyser. In a little time, the water reascends to its usual level, and there remains for the next day or two, with only those minor disturbances which have been described.

The thermal springs and wells of Iceland may be said to be of three classes—1. Those of continual and uniform ebullition; 2. Those which, while not constantly ebullient, are liable to occasional eruptions; and, 3. Certain wells not yet particularised, which contain tranquil tepid water, but are supposed (at least in some instances) to have formerly been eruptive. It is only in regard to the second class that there is any room for doubt or speculation. To what are we to attribute the occasional eruptions?

The theory started by Sir George Mackenzie, who visited Iceland in 1810, is, that steam is gathered in some cavernous recess connected with the subterranean channels through which the water rises; and that, when it has accumulated there till such time as the pressure overcomes the resistance, it bursts forth through the tube, carrying the water before it, and tossing it high into the air. This mechanical theory, as it may be called, has lost ground since the announcement of a chemical one by Professor Bunsen, who spent eleven days beside the Great Geyser in 1846. The learned German looks for an explanation of the phenomena to the molecular changes which take place in water after being long subjected to heat. 'In these circumstances,* water loses much of the air contained in it; the cohesion of its molecules is greatly increased, and a higher temperature is required to boil it. When water in this state is brought to the boil, the production of vapour is so instantaneous and so considerable as to cause an explosion. It has been found that the water of the Great Geyser at the bottom of the tube has a temperature higher than that of boiling water, and this goes on increasing till an eruption takes place, immediately before which it has been found as high as 261° F. This peculiarity—for so it is, seeing that, in ordinary circumstances, the hotter water at the bottom would rise to the top till all was equally warm—shews that the heating of the water in the Geyser takes place under extraordinary circumstances. As far as I understand Professor Bunsen, he implies that the great pressure of the column above, and perhaps some mechanical impediments to free circulation in the form of the Geyser, give these required circumstances. Such being assumedly the case, there is an increase in the cohesion of the molecules of the water constantly going on at the bottom, at the same time that the heat is constantly increasing; at length, the latter force overcomes the former—ebullition takes place—an immense volume of vapour is instantaneously engendered, and an eruption is the consequence.' We have to consider this theory in an unusually curious light in connection with a small double geyser, as it may be called, which exists in the group at Reikholt, and in which each pool makes an eruption every few minutes, the other being at those times pacific.

The water of the Great Geyser contains soda in various forms; but the chief ingredient is a charge of about 31 grammes of silica to six gallons. This forms the incrustations around the pools, reaching to the bulk of a little hill in the case of the Great Geyser.

GFRÖRER, AUGUST FRIEDRICH, a German historian, was born at Calw, in the Black Forest, 5th March 1803. Although he studied for the church, he had lost all taste for its practical work when he completed his theological education in 1825. After spending some time at Lausanne and Geneva, where he mastered the French language, he went to Rome in 1827 to study Italian. On his return next year, he became a *Repetent*, or tutor, in the theological institution at Tübingen; in 1829, he was removed to a similar situation in Stuttgart; and in 1830, he was appointed national librarian. He now abandoned ecclesiastical life entirely, and devoted himself to literature. The first fruit of his studies was a work on Philo and the Judæo-Alexandrian Theosophy in their relation to the doctrine of the New Testament (*Philo und die Jüdisch-Alexandrinische Theosophie*, 2 Bde., Stutt. 1831). This formed the first part of a larger work on the History of Primitive Christianity (*Gesch. d. Urchristenthums*), which was completed in 1838 in three other parts. Between the beginning and completion of this work, G.'s views on Christ and Christianity had undergone a change, which appeared also in his History of Gustavus Adolphus and his Times (*Gustav Adolf, König von Schweden, und Seine Zeit*, Stutt. 1833—1837), for the first edition of that work takes at the commencement the side of the Guelphs, and towards the close, that of the Ghibellines—an impropriety which was corrected in the second edition (1844—1845). After a work on the *Propheta Veteres Pseudepigraphi* (Stutt. 1840), G. published his *Allgemeine Kirchengeschichte* (Stutt. 1841—1846), which has reached the 7th vol., and brings church history down to 1305. While working at this history, he came to the conviction that the true church is the historical, i. e., the apostolical Roman Catholic, and that the Reformation originated to a large extent in misunderstanding and the ambition of princes. He was accordingly called in 1846 to the Catholic university of Freiburg, and there, by his zeal in defending the interests of the university, was drawn into manifold conflicts, which were fought again more earnestly at the Frankfurt parliament in 1848, where he was one of the most decided adherents of the party called the *Grossdeutschen*. In 1848 appeared his History of the Carolingians of Eastern and Western Franconia (*Gesch. d. ost- u. westfränkischen Karolinger*, 2 Bde., Stutt.); in 1855, the first two volumes of a work on the Early History of Mankind (*Urgesch. d. menschlichen Geschlechts*, Schaff.); and in 1861 the concluding volume of a large work on the times of Gregory VII. (*Papst Gregorius VII. und Seiner Zeit*, 7 Bde., Schaffh.).

GHAMBARU, formerly a celebrated town of Africa, in the state of Bornu, in lat. 13° 5' N., and long. 12° 5' E. During the flourishing period of the Bornuese empire, it was the favourite retreat of the kings of the country. It was taken and destroyed by the Fulahs in 1809, and since that date has remained in a state of utter ruin and desolation; so that now almost all traces of the town have become covered with vegetation, and enveloped in the surrounding forest. The most interesting relic of G. is a well-preserved portion of an ancient edifice, evidently a mosque. This mosque was built of bricks, which, although not so regularly shaped as European bricks, are in other

* This account of Bunsen's theory is from a series of articles entitled *Tracings of Iceland*, which appeared in *Chambers's Journal* in 1855, and subsequently in a small 8vo volume, 1s., published by W. and R. Chambers.

respects said to be quite as good. G. stands in the midst of a district comprising the finest land of Bornu, and which, before the beginning of the present century, was loud with the noise and bustle of hundreds of towns and villages; now, however, it is the haunt of the elephant and the lion; the silence of solitude has overspread it, and it has sunk back into the condition of the primeval jungle.

GHARA, formed by the junction of the Sutilj and the Beas, the most easterly of the rivers of the Punjab, unites with the Chenab, which has previously collected the remaining three of the five, to form the Punjnad, which thus carries the whole into the Indus. The distance between the two points of confluence is about 300 miles. The G. is nowhere fordable at any season; and its breadth varies from 200 yards to 500.

GHASEL, or GHAZEL, a favourite form of lyrical poetry among the Turks and Persians. It is composed of not less than five, and not more than seventeen strophes of two lines each, all the second lines of which rhyme together. The last couplet always contains the real or assumed name of the author. In regard to matter, the ghaseel is either purely erotic and bacchanalian, or allegorical and mystical. Western scholars regard it as the Oriental sonnet. Hafiz is unsurpassed in this kind of verse, and it has also been happily imitated by the German poets, Platan, Rückert, Bodenstedt, &c.

GHÂTS, or, as usually written, GHAUTS, are buildings erected along the banks of rivers, in order to afford easy access to bathers. They are peculiar to Northern Hindustan, and line the river banks in most of the great cities, more especially those situated on the Ganges. A ghât consists in general of a long, high building, fronting the river, to which access is had by means of several flights of steps, these latter forming the essential part of the structure, as the wall or building is only for the protection of loungers from the sun's rays. The uniformity of the long lines of steps is broken by small projections, often crowned by kiosks, which relieve the eye. 'Upon these ghâts,' says one traveller, 'are passed the busiest and happiest hours of a Hindu's day. Escaping from the narrow unwholesome streets, it is a luxury for him to sit upon the open steps, and taste the fresh air of the river; so that on the ghâts are concentrated the pastimes of the idler, the duties of the devout, and much of the necessary intercourse of business.' Though the Ganges, being the sacred river, is *par excellence* the river of ghâts, one of the most beautiful in Hindustan is that erected at Maheswar, on the Nerbudda, by Alaya Baicee, the widow of Holkar; and though Benares prides itself upon possessing the greatest number of ghâts, it is almost rivalled by Ougain and other cities. For a fuller account of these structures, see Fergusson's *Hand-book of Architecture*.

GHAUTS (in English, *Gates* or *Passes*) are two converging ranges of mountains, which run parallel with the east and west coasts of the peninsula of Hindustan, and hence known as the *Eastern* and *Western G.*—1. The Eastern G. extend, with an average height of 1500 feet, from the vicinity of Balasore, in lat. 21° 30' N., a little north of the Mahanadi, to within 20 miles of Cape Comorin. Before joining the kindred ridge at this last-mentioned point, they send forth, about 36 miles to the north of Madras, a common spur, as it were, of both ranges, which reaches the other range to the north of the gap of Palghatcheri. To the south of the departure of this connecting chain, the Eastern G. become less continuous and distinct. Moreover, they

are nowhere a water-shed on any considerable scale, being penetrated and crossed by nearly all the drainage of the interior.—2. The Western G. stretch from the south side of the Tapti, about the same latitude as Balasore, to their junction with the kindred ridge, at a distance of 20 miles from Cape Comorin, or rather, in fact, to Cape Comorin itself. Though they are generally far more continuous and distinct than the G. Eastern, yet they are sharply divided by the gap of Palghatcheri, 16 miles broad—the northern section measuring 800 miles in length, and the southern 200. Their general elevation appears to vary from about 4000 feet to fully 7000. The peak of Dodabetta in that portion of the Western G. known as the Neilgherries, is said to be 8760 feet above the level of the sea. The opposite faces of these mountains differ very remarkably from each other. Landward, there is a gradual slope to the table-land of the Deccan; seaward, almost perpendicular precipices, speaking generally, sink at once nearly to the level of the sea, at a distance from it ranging from 40 to 70 miles, but at one place approaching within 6 miles. From this peculiarity, aggravated, as it is, by the incredibly heavy rains which the south-west monsoon dashes against the lofty barrier before it, the maritime strip, more particularly towards the south, presents that singular feature of the country which is known as the 'Backwaters.' See COCHIN. The Western G. are, with hardly an exception, a water-shed, for not a single stream of any magnitude finds its way through them.

GHAZIPO'RE, a city of Hindustan, capital of a district of the same name, stands on the left bank of the Ganges, in lat. 25° 32' N., and long. 83° 39' E. It contains about 8000 inhabitants. The mean temperature of May, the hottest month, is 97° F.; and of January, the coldest month, it is 56°. The air is said to be comparatively salubrious. The place owes this advantage to the porous character of the soil; and it has, moreover, a long reach of the river towards the south-east—the quarter from which the hot winds generally blow.

GHAZZA'LLI, ABU HÂMID MOHAMMAD IBN AHMAD, surnamed ZAINEDDIN (glory of the law), one of the most eminent Mohammedan philosophers and divines, and one of the warmest adherents of Sufism (q. v.), born in 450 H. (1058 A.D.) at Tus, in Khorassan, the birthplace also of Firdusi, and burial-place of Harun-al-Rashid. The surname of G. was given to him, according to some, because his father dealt in *ghazal* or spun cotton. Left an orphan at an early age, by the advice of his guardian, a Sufi, he went to Djorshan, with the intention of devoting himself to study and science, as a means of support, and became the favourite pupil of Abu Nasr Ismail, an eminent teacher of the time. He afterwards betook himself to Nishapur, where he attended the lectures of the learned Imam of the two sanctuaries (Mecca and Medina) on law, polemica, philosophy, and theology, and remained till the death of his instructor. The grand vizier of Bagdad then appointed him (1091 A.D.) to a professorship at his *Nizamié* (university), which he left four years later, in order to perform the holy pilgrimage to Mecca. On his return, he visited Jerusalem and Damascus, and remained for ten years at the mosque of the latter place, leading a studious and ascetic life. He afterwards visited Cairo, Alexandria, and other places in Africa, everywhere teaching and lecturing on religion and science, and also returned for a short time to Nishapur; but he finally went back to Tus, his native place, where he died 505 H. (1111 A.D.)

having founded a monastery for Sufis, and a college for the studious.

Of the ninety-nine works written by him (mostly in Arabic, a few in Persian), the most famous is his *Ihyá Olám ad-Dîn* (Restoration of Religious Sciences), a work so remarkable and exhaustive, that it has been said: 'If all the books of the Islam were lost, and we had only this one left, we should not miss the others' (*Haji Khalifah*). The academies of the West, however, Cordova, Morocco, Fez, &c., condemned it as contrary to the teachings of the Sunna (q. v.), and had it publicly burned. Next in importance stands his great philosophical work *Taháfut Al-Filásafah* (The Overturning of the Philosophers), which has survived only in Hebrew translations, and which gave rise to a warmly contested controversy between him and Averroës (Ibn Roahd). We may mention also his commentary on the ninety-nine names of God, and an ethical treatise, *O Child!* published and translated into German by Hammer-Purgstall. About one-third only of his works is known to have survived, and of this but a very small part has been published.

GHEE, a kind of butter used in many parts of India, and generally prepared from the milk of buffaloes. The fresh milk is boiled for an hour or more; it is then allowed to cool, and a little curdled milk, called dhye, is added to promote coagulation. The curdled mass is churned for half an hour; some hot water is then added; and the churning continued for another half hour, when the butter forms. When the butter begins to become rancid, which is usually the case after a few days, it is boiled till all the water contained in it is expelled, and a little dhye and salt, or betel-leaf, is added; after which it is put into closed pots to be kept for use. It is used to an enormous extent by the natives of many parts of India, but is seldom relished by Europeans.

GHEEL, a well-known colony for the insane, is a town of Belgium, in the province of Antwerp, and 26 miles east-south-east of the town of that name. It is literally an oasis in a desert; a comparatively fertile spot, inhabited and cultivated by 10,000 or 11,000 peasants, in the midst of an extensive sandy waste, called the Campine, where neither climate, soil, nor surroundings invite a settlement. There are no gentlemen's seats in the district, and the farmhouses, though neat, and generally surrounded by trees and a garden, are evidently in the hands of the poor. Their frequency shews this. They are sometimes built of brick; much more generally, they are constructed of wattled or wicker work, thickly laid over with mud or plaster, and whitewashed. A G. crofter's house is much larger than the dwelling of a small farmer in Scotland. The people inhabiting these seem to be about the rank of English cottagers, but are inferior in aspect, tone of character, and cleanliness of habits. The dwellings are arranged into three classes, or cordons: those of the village proper; those scattered around in its immediate vicinity; and those collected into hamlets in the more distant and least reclaimed portions of the commune, which may be about 20 miles in circumference.

Historically considered, G. is noted as having been the spot where a woman of rank, said to have been of British origin, was murdered by her father, in consequence of her resistance to his incestuous passion. The pagan in his revenge gave the church a martyr. Pilgrims, the sick, the sorrowful, and the insane, visited the tomb of the Christian virgin; the last were restored to sanity and serenity. Dymphna became the tutelary saint of those stricken in spirit; a shrine rose in her honour, which now,

for ten centuries, has been consecrated to the relief of mental disease, is said to have been distinguished by never-failing success, and, at all events, has collected around it hundreds of lunatics, chiefly of the poorer classes, but labouring under every form and stage of nervous malady. Formerly, besides the benefit derivable from proximity to the ashes of the saint, and from the prayers of the church, the afflicted underwent a sort of novitiate in a building adjoining the church, where they were chained to the wall, and subsequently passed under the mausoleum of their patron, &c.; but now, although faith lingers, there do not appear to be any other than the ordinary ministrations of the church to which the patients belong, resorted to as treatment.

About 800 insane persons are lodged with the citizens of this community, or with 600 heads of families, and are controlled and employed by them, and this without recourse to walls or ha-has, or other asylum appliances, and with little coercion of any kind. The quiet and industrious reside generally one in each family in the town, the more excited in the suburban cottages, and the most unmanageable with the labourers on the confines of the commune. The effect produced by this large body of lunatics wandering, working, displaying many of their peculiarities in the midst of a thriving sane population, who chiefly depend upon a traffic in insanity, is both striking and picturesque. In the enjoyment of comparative liberty, and of what is called the free-air treatment, these patients are, upon the whole, contented, tranquil, and healthy. Violence is rare; only two suicides have occurred in four years; and morality is less outraged than in more protected classes. Each individual is maintained for about 64*d.* to 74*d.* *per diem*. Until recently, this colony was merely a psychological curiosity; recently, the anomaly and absurdity of treating all cases alike, and independently of medical aid, have led to the institution of a medical staff, the erection of an hospital, and the introduction of many salutary alterations in the relations between the insane and their custodiers, in classification and supervision. The compatibility of the seclusion of the insane with greater freedom, with domestic life, and association with the sane, have suggested the introduction of cottage asylums, as a modification in the accommodation of this class in this country. (*Gheel ou une Colonie d'Aliénés vivant en famille et en liberté*, par M. Jules Duval. Paris, 1860.)

GHENT (Flem. *Gend*, Ger. *Gent*, Fr. *Gand*), an important city of Belgium, capital of the province of East Flanders, is situated at the confluence of the Lys and the Scheldt, 31 miles west-north-west of Brussels. It is divided by canals into 26 islands, connected by 270 bridges, and is encompassed with gardens, meadows, and pleasant promenades. It is surrounded by walls, pierced by seven gates, and enclosing an area eight miles in circuit, and is in general well built; but in the older part its quaint and fantastic houses render it in the highest degree picturesque. Among the chief buildings are the Church of St Bavon, containing the famous 'Adoration of the Lamb,' by the brothers Van Eyck; the new citadel, finished in 1830; the Palace of Justice, built in 1844, and having a peristyle of the Corinthian order; the university, connected with a school for civil engineering, and for trades and professions; the Beguinage, a convent containing about 700 nuns; the royal Gymnasium; and the Academy of Painting. The cotton and woollen manufactures are carried on on a great scale. There are about 60 cotton-mills, and upwards of 15,000 workmen are employed in the spinning, printing, dyeing, and

weaving of cotton, woollen, and linen fabrics. Leather and paper are also manufactured, and a flourishing trade is carried on in floriculture. Eight extensive flower-dealers are engaged in this branch of trade, and upwards of 400 hothouses are required. The commerce of G. is important. By the Great Canal, which flows into the Scheldt, it is united with the sea, and it can receive into its docks vessels drawing 18 feet of water. The new dock or basin on the north-east side of the city is capable of holding 400 vessels. Pop. 109,618.

G. is mentioned in history as early as the 7th century. About the year 868, Baldwin Bras-de-Fer, the first Count of Flanders, built a fortress here as a defence against the Normans. Under the Counts of Flanders, G. continued to prosper and increase, until, in the 14th c., it was able to send 50,000 men into the field. The wealth of the citizens of G., and the unusual measure of liberty which they enjoyed, encouraged them to resist with arms any attempt to infringe upon their peculiar rights and privileges. This readiness to arm in their own defence is exemplified in the famous insurrection of Jacob van Artevelde (q. v.), and other instances. For many years, it maintained a vigorous, but unavailing resistance against the Dukes of Burgundy—who wished to be recognised as Counts of Flanders—and the kings of Spain. In the various wars of which the Netherlands has been the battle-ground, G. suffered severely, and was frequently taken. In 1792, the Netherlands fell under the power of France, and G. was made the capital of the department of the Scheldt, continuing under French dominion until the fall of Napoleon, in 1814, when it was incorporated with Flanders in the kingdom of the Netherlands.

GHERARDESCA, a family of Tuscan origin, which enacted a conspicuous part in the history of the Italian republics during the middle ages. Their vast territorial possessions lay between Pisa and Piombino. In the 13th c., the Counts G. exercised a preponderating authority in the republic of Pisa, and were prominent supporters of the popular interests, in opposition to the encroachments of the nobles. In the great feud between the Guelphs and Ghibellines, they became warm partisans of the latter, and were the irreconcilable enemies of the Visconti, who headed the Guelphs. The most famous of this family, both with respect to the historical events of his career, and the appalling tragedy of his fate, is Count Ugolino, whose name and fate have been invested with undying interest by Dante. Count Ugolino, more than any of his race, was possessed by a lawless ambition, and a subtle, unscrupulous spirit. Having resolved to usurp supreme power over Pisa, he formed an alliance with Giovanni Visconti, the head of the Guelphic party, who promised to supply him secretly with soldiers from Sardinia. The plot was, however, discovered, and both Giovanni and Ugolino were banished from the city. The former died soon after; but the latter, uniting himself with the Florentines and the Lucchese, forced the Pisans, in 1276, to restore him his territories, of which he had been deprived. No sooner was he reinstated in his possessions than he began to devise anew ambitious schemes. The war of the Pisans with the Genoese afforded him the opportunity he desired. In the battle fought at the island of Malora, 6th August 1284, Ugolino, by treacherously abandoning the Pisans, occasioned the complete annihilation of their fleet, together with a loss of 11,000 prisoners. When the news of this disaster spread, the Florentines, the Lucchese, the Siennese, the Pistoians, and all the other enemies of the Pisan republic, gathered together to destroy it, as the stronghold of the

Ghibellines in Italy. Being thus brought to the brink of ruin, the Pisans had no other resource left than to throw themselves into the arms of him whose treachery had reduced them to such misery. From the time of his election, he gave free scope to his vindictive, despotic nature, persecuting and banishing all who were privately obnoxious to him, on pretexts of state delinquency, till at length a conspiracy was formed against him, headed by his former supporter, the Archbishop of Pisa. Dragged from his palace, 1st July 1288, after a desperate defence, he was thrown into the tower of Gualandi, with his two sons and two grandsons, where they all perished amid the agonies of starvation, for which reason their dungeon has since borne the ominous name of the 'Tower of Hunger.' In spite of this, the family again rose into importance; and in 1329 we find *Nieri Donatatico G.* at the head of the republican authority in Pisa. See Sismondi's *History of the Italian Republics*.

GHIBELLINES. See GUELPHS and GHIBELLINES.

GHIBERTI, LORENZO, a famous Italian sculptor, was born at Florence about 1378. He was educated in art by his stepfather, a skilful goldsmith, and rapidly acquired dexterity in drawing, painting, and modelling. At the age of 19, he was selected for the execution of a noble fresco in the palatial residence of Prince Pandolfo Malatesta at Rimini. Along with seven other artists, he was next chosen by the Florentine guild of merchants to compete for the execution of a splendid gate in bronze, to suit that executed by Andrea Pisano in the baptistery of Florence, about 1340. The subject of the design was *The Sacrifice of Isaac*, to be executed in bas-relief as a model for one of the panels. The judges found a difficulty in deciding between Brunelleschi, Donatelli, and G., but the two former generously proclaimed the superiority of G.'s design, both with respect to the art and beauty of its conception, and the delicacy and skill of its execution. When G. had completed his great work, his fellow-citizens intrusted him with the execution of another gate, to emulate the beauty and colossal dimensions of the two already adorning the baptistery. From Michael Angelo, G. received a noble tribute of admiration, when the great artist asserted that *the two gates were worthy of Paradise*. G.'s second gate contains ten reliefs on a larger scale, the subjects in this case also being wholly biblical. The mingled grace and grandeur of these compositions are beyond all praise. Not the least of G.'s merits was the success that attended his efforts to break up the conventionalism that before his day hampered the free development of sculptural art. Among his other works may be mentioned a bronze relief in the Duomo at Florence, representing San Zenobi bringing a dead child to life, and bronze statues of St John the Baptist, St Matthew, and St Stephen. G. died at Florence in 1455.

GHİKA, a princely family of Albanian origin, which has given many hospodars to Moldavia and Wallachia. The founder of the House was George G., an Albanian by birth, who, through the favour of his compatriot, the grand vizier, Mohammed Kiupruli, was raised to the dignity of Hospodar of Wallachia in 1657. He was succeeded by his son Gregory G., who ruled, with various vicissitudes, till 1673, and received from the Emperor Leopold I. the title of Prince of the Holy Roman Empire. Of subsequent members of the family, the only ones calling for special notice are Alexander, Gregory, and Helena.

ALEXANDER GHİKA IX. was born in 1795, and, through the influence of the Russian Count Kisseleff,

was elevated to the hospodar of Wallachia in 1834. Nevertheless, he soon exhibited liberal and enlightened tendencies. He founded schools for primary instruction in every village, lightened the burdens of the peasantry, commenced the enfranchisement of the gipsies, and assisted in the organisation of a national party, since known as *Young Roumania*. Russia naturally took the alarm, and gradually, under her influence, a twofold opposition was excited against him, viz., an opposition of the extreme liberals, and also of the old boyards (the landed proprietors), who formed the Tory party, and were his personal enemies; the result of which, after many intrigues and plots, was that, in 1842, he was ordered to resign his dignity by the Turkish sultan. He now betook himself to Vienna, where he lived quietly till 1853, when he returned to Wallachia, to find himself once more popular; and in 1856 he was elected 'Caimacam' of the principality, to the great joy of the young Roumanian party both in Moldavia and Wallachia.

GREGORY GHICA X., hospodar of Moldavia, born at Botochani, in Moldavia, 25th August 1807, was appointed *Hetman*, or commander-in-chief of the militia, in 1828, Secretary of State in 1842, and Minister of Finance in 1843, under the hospodar of Michael Stourdza. But as the system of the government became more and more Russian in its character, he resigned his functions, and passed into the ranks of the liberal opposition, of which he soon became one of the chiefs. In 1849, the sultan appointed him hospodar, in order to counteract the influence then exercised by Russia in the adjoining principality. His tenure of office may be divided into three distinct periods. In the first, his efforts at reform were crippled by the presence of Russian troops in the Principalities, in violation of the convention of Balta-Liman. The second, commencing with the departure of the Russians in 1851, was marked by many excellent measures; he organised a good police system, augmented the effective force of the militia, founded schools for superior and secondary instruction at Niamtzo, Houch, Galatz, &c., promulgated an administrative code—the first great step towards the reform of abuses—increased municipal resources, and at his own expense built aqueducts, and printed important historical MSS. The re-occupation of the Principalities by Russia in 1853 suspended his labours, and resigning the hospodarat provisionally, he withdrew to Vienna, but resumed his functions in the end of the following year. The third period of G.'s rule was initiated by the formation of a liberal ministry, by the support of which he effected, among other things, a radical reform of the penitentiary system, the abolition of serfdom (1855), and of the censorship of public journals (1856), and the establishment of foreign merchant companies for the navigation of the Pruth and the Sereth (1856); while he also encouraged the growth of a union feeling among the Roumanian party in both principalities. His tenure of office expiring in 1856, G., whose private fortune had been rather diminished than increased by his dignity, quitted Moldavia, and went to reside in France. His death occurred in the end of July 1857.

HELENA GHICA, Princess Koltzoff-Massalsky, better known by her literary pseudonym of *Dora D'Istria*, is niece of Prince Alexander Ghika, ex-hospodar of Wallachia, and was born at Bucharest, 22d January 1829. Profoundly instructed in the classics under the care of George Pappadopoulos, she added to these, by frequent travels through Germany, France, and Italy, an extensive knowledge of modern languages and literature, and at the age of 15 commenced a translation of the *Iliad* into German,

and not long after wrote several pieces for the theatre. On her marriage with Prince Koltzoff-Massalsky, who belonged to one of the oldest Russian families, she accompanied her husband to the court of St Petersburg. Since 1856, however, she has fixed her residence at Aarau, in the canton of Aargau, in Switzerland, and devotes herself wholly to literary labour. Her first important work, *La Vie Monastique dans l'Eglise Orientale*, was published at Paris and Geneva in 1855. This was followed by two works written in Italian, *Gli Eroi della Rumenia* (The Heroes of Roumania) and *I Rumeni ed il Papato* (The Roumans and the Papacy). Her studies in Switzerland have also resulted in a volume entitled *La Suisse Italienne*. Besides these, she has also contributed largely to various foreign reviews. Her religious writings are marked by a pious faith in the great doctrines of Christianity, an indifference to outward forms, and a tendency to mysticism, while her political opinions are liberal to a degree that scandalised the court of St Petersburg during her residence there.

GHILAN, a border province of Persia, consists of the south-western portion of the narrow strip of country lying between the Elburz range and the Caspian Sea. It extends between lat. 36° 30' and 38° 30' N., and long. 48° 33' and 50° 30' W. It is upwards of 150 miles in length, and about 70 miles at its broadest part. The province is subject, from the lowness of the land, to frequent inundations, and indeed during greater part of the year is little better than a swamp. Forest and mulberry trees, with some rice, are grown. Its extent in square miles, and its population, have not yet been ascertained. The climate is unhealthy.

GHIRLANDAJO, or CORRADI, DOMENICO, an eminent painter of the early Florentine school, was born at Florence in 1451. From his youth, he was educated to the craft of the goldsmith by his father, who received the name of Ghirlandajo on account of his being the inventor of some silver ornaments of great elegance, in the form of a wreath or *ghirlanda*, which became the favourite head-dress of the Florentine beauties of his day. At the age of 24, G. abandoned working in gold, and set about qualifying himself for the calling of a painter. He lived to become not only a famous and lauded artist, but also one of the most progressive and original masters of his age. His greatest works are frescoes, but he has also left fine easel paintings, both in oil and distemper, and his composition in mosaic—or 'eternal painting,' as he termed it—are unrivalled for the brilliant dyes of the colouring and the delicate softness with which they are blended and graduated. The Capella di Sassetti, in Florence, contains a noble series of G.'s frescoes, illustrative of both historical and legendary incidents in the life of St Francis. They are strongly characterised by the wonderful mastery of intense and varied human expression, which, more than accurate delineation of form, was the great merit of G.'s paintings. The Church of Santa Maria Novella is also rich in this artist's works, being adorned by a set of frescoes representing scenes from the life of St John the Baptist, many of the figures introduced being correct likenesses of some of the leading celebrities of the day. G. was the first artist who adopted correct principles of perspective, just gradations of shade and form, and dramatic art in grouping. G. died at the early age of 44, in the year 1495.

GHIUSTENDIL, a town of European Turkey, in the eyalet of Rumili, is situated on the slope of a hill about two miles distant from the right bank of the Struma or Kara Su, 192 miles in direct line

west-north-west of Adrianople. It is surrounded by an old wall flanked with towers, is the see of a Greek bishop, and contains a bazaar and sulphurous baths. Pop. 10,000.

GHIZEH, or **GIZEH** (Coptic, *Tperoi*), a village in Egypt, close to the northern border of Middle Egypt, on the opposite side of the river and about three miles west-south-west from Cairo. In the immediate vicinity, the line of great pyramids commences. See **PYRAMID**. Here one may still witness the process of egg-hatching in ovens, a practice which has been continued from the time of the Pharaohs to the present day. G., formerly adorned with beautiful palaces and mosques, the pleasant retreat of the Cairo merchants, is now a mere village, and mounds of rubbish are almost the only indication that buildings of some pretension once existed here.

GHIZNEVIDES, a celebrated dynasty, which, in the height of its power, possessed an empire extending from the Tigris to the Ganges, and from the Sihon or Sir-Daria to the Indian Ocean. The founder of the dynasty was Alekteghin, originally a slave belonging to Abdulmelek, the Samani Ameer of Bokhara, who was appointed governor of Khorassan; but on the death of his benefactor he rebelled, and proceeded at the head of an army to Ghizni, of which he took possession in 961, and for 15 years successfully withstood the whole power of the Samani (q. v.). On his death, Sebekteghin or Sebectagi was unanimously chosen as his successor. He was distinguished for his prudence and valour, and equally so for his humanity and justice. By him the kingdom was extended from the Indus to Khorassan, and from the Gulf of Oman to the Amu-Daria or Jihon; and in the latter province his son, Mahmud, was appointed governor under the nominal suzerainty of the Samani. Sebekteghin died in 997, and was succeeded by his younger son Ismail; but Mahmud the elder, hearing of his father's death, hastened to Ghizni, and assumed the reins of government in 998, with the title of Sultan. In the year following, he took complete possession of Khorassan, and in 1001 commenced a series of destructive inroads into Hindustan. Falling in with Jeypal, the prince of North-Western India, at Peshawar, Sultan Mahmud, on the 8th of Mohurrim (November 26), defeated him with immense slaughter. In 1004, while on his second expedition to India, he was recalled by the news that Eylek Khan of Khashghar, who in 999 had conquered the Samani and taken possession of their territory, was ravaging Khorassan and Balkh; on hearing which, Sultan Mahmud, leaving his conquests, returned in an incredibly short time to Ghizni, and thence proceeding without delay to Balkh, engaged in battle with the enemy, and completely defeated them. He then took possession of the country between the Sihon and the Jihon (ancient Transoxiana). In 1007 and 1009, Sultan Mahmud made his third and fourth expeditions into Hindustan, and each time carried off an immense booty in money, jewels, and slaves. On his return to Ghizni, he made a liberal distribution from his treasures among the poor and the ministers of religion. About this time he reduced Ghur, Gherjistan, and Khaurezm, bestowing the latter province upon Altun-Taush, one of his favourite generals. In 1024, he was engaged in his last expedition against the Hindus, the famous expedition to Somnaut (q. v.), at the southern extremity of Guzerat. Mahmud here obtained an enormous booty. In 1027, he received from the Calif Ul Kader a ratification of all his conquests, together with numerous titles of honour, and in the two following years having conquered Irak, Tebristan, and Mazan-

deran, he returned to his capital, where he died on the 29th of April 1030. At this time, the empire of Ghizni was at the summit of its glory, having in the short space of 69 years extended over 38 degrees of longitude and 20 of latitude. Mahmud possessed some of the most exalted qualities that dignify and adorn human character, but they were much obscured by his sanguinary zeal for the advancement of Islam. He was succeeded by his younger son Mahomed who in October of the same year was compelled to resign the sovereignty to his elder brother, Mussad I. This prince was in 1087 signally defeated by the Seljucks (q. v.), who had taken possession of Khorassan under Toghrul Beg and Tchegher Beg, the grandsons of Seljuk. Though an able and warlike prince, misfortunes crowded thickly round his declining years, and in 1041 he was put to death. During his reign, the Seljucks took possession of Balkh, Khorassan, Khaurezm, Herat, and Irak. The sovereigns who in succession reigned in Ghizni were Muddud (1041—1049), Mussad II. (1049), Ali (1049—1052), Abdurrashid (1052—1053), and Furrukhzaud (1053—1058), during whose reigns there is nothing worthy of relation, beyond the intestine quarrels at Ghizni, and the encroachments of the Seljucks on the west and north. The reign of Furrukhzaud, however, shed a bright lustre over the expiring glory of Ghizni, for the Seljuk prince, Daoud, thinking to take advantage of the dissensions at Ghizni, marched towards it; but on the way he was met by Nusatkekin, one of the best generals of the age, and signally defeated. Taking advantage of this victory, Nusatkekin marched into Khorassan, to recover that province, and encountering Kelliasurek, a celebrated Turkman chief, totally defeated him. On news of this second defeat, Alp-Arslan (q. v.) was sent by his uncle Toghrul Beg to stop the progress of the G.; and in the battle which ensued, fortune changed sides, and Nusatkekin was totally defeated. A treaty of peace was then concluded. Furrukhzaud was succeeded by Ibrahim (1058—1098), Mussad III. (1098—1114), Arslan Shah (1114—1118), and Behram Shah (1118—1152). During the reign of this last prince, the Ghuri, a tribe inhabiting the mountainous country of Ghur, began to make inroads upon the territory of Ghizni, and growing bolder by success, attacked and took the capital itself, driving Behram Shah across the Indus. But on the retreat of part of the Ghuri to their own country, Behram Shah returned and retook his capital, making prisoner the Prince of Ghur, Seyfuddeen Souri, whom he put to death with the most refined cruelty. On learning this, the brother of the unfortunate prince, Allah-ud-deen, hastened from Ghur, and having defeated Behram Shah, gave up Ghizni to be pillaged by his followers. Behram Shah, thus driven a second time across the Indus, desisted from all further attempts to regain his ancestral dominions, and died in 1152. His son, Khosru Shah succeeded him, and took up his residence in Lahore; but the many attempts which he made to repossess himself of Ghizni and the surrounding territory were unsuccessful. Khosru Melek, the seventeenth and last monarch of the dynasty of Ghizni, occupied himself in the first part of his reign (1160—1166) in extending and consolidating his Indian possessions, but subsequently his whole energies were required to repel the attacks of Shahab-ud-deen Mahomed, Prince of Ghur, who, having conquered all the territory west of the Indus, now sought to drive the race of Sebekteghin from their last possession. In 1184, Lahore was all that remained to Khosru Melek, and the taking of that city by the Ghurian prince in 1186 put an end to the power of the Ghiznevides.

GHIZNI, a river of Afghanistan, loses itself, after a southerly course of about 80 miles, in the salt lake of Abistada, which is 7076 feet above the sea. Its source is 12 miles to the north of the city of its own name, and its mouth is about lat. 32° 35' N., and long. 68° E. Its embankments, dating from the 11th c., are still fit for the purposes of irrigation.

GHIZNI, the city mentioned in the preceding article, stands at an elevation of 7726 feet, on a scarped rock, which rises 280 feet above the adjacent plain. Its natural strength has been increased by walls of 35 feet in height, and a wet ditch. It has long been a place of importance in Central Asia, having been, in the 11th c., the seat of an empire (see **GHIZNEVIDES**). Some of the most interesting points in its history, however, are much more recent. In the July of 1839, G. was stormed by the British under Lord Keane; and in 1842 it was first surrendered to the Afghans, and then retaken by General Nott. Eventually it was restored, with the rest of the country, to Dost Mohammed. It is situated in long. 68° 18' E., and lat. 33° 34' N.—a parallel which, under the influence of the remarkable altitude of the spot, yields, in winter, a temperature of about 20° Fah. below zero. The population has been variously estimated up to 10,000, fluctuating most probably with the season of the year. G. is an entrepôt of the trade between Afghanistan and the Punjab.

GHO'GRA, or **GHAGRA**, one of the largest affluents of the Ganges, joins that river from the left in lat. 25° 48' N., and long. 84° 40' E., after a generally south-east course of 600 miles. It rises in lat. 30° 28' N., and long. 80° 40' E., on the southern declivity of a mountain-range, which separates the district of Kumaon from South-West Tibet. The actual source, being between 17,000 and 18,000 feet above the sea, is hidden under perpetual snows at every season, while in winter it can scarcely be said to flow at all. Throughout the first 50 miles, the torrent, tumbling as it does down deep gorges, is in many places entirely concealed by glaciers. After receiving many tributaries on both sides, it enters the great plain of Hindustan in lat. 29° 6' N., and long. 80° 13' E., being now, after a run of 148 miles, 798 feet above the sea. Here it has been estimated to be about two-thirds of the size of the Ganges at the corresponding point of Hurdwar. Hitherto it has generally formed the boundary between Kumaon and Nepal. Before the G. has descended 70 miles further, it has become navigable for craft of considerable burden. Further down, it is practicable for boats of all sizes at every season, but is here and there beset by dangerous and intricate shoals. Like other great rivers traversing alluvial tracts (see **GANGES**), it sends off lateral water-courses, which in the rainy season communicate with the parent-flood and with each other. The principal auxiliaries, to take them in order, are the Kalipani on the left; the Dhoul, on the right; the Gorigunga, also on the right; the Chumalea, on the left; the Western Surju, on the right; the Lohogatain, on the right; the Ladhia, the last of its hill-tributaries, also on the right; the Kurnalli, on the left; the united Chonka and Woel, on the right; the Eastern Surju, on the left; and finally, the Rapti, also on the left.

GHOST-MOTH (*Hepialus humuli*), a species of moth very common in many parts of Britain, and of which the caterpillar—popularly known as the **OTTER**—often commits great ravages in hop plantations, devouring the roots of the hop. It feeds also on the roots of the nettle, burdock,

and some other plants. This moth belongs to a family (*Hepialidae*) often popularly called *Swifts* from their rapid flight, having long narrow wings, and destitute of a tongue. The antennae are short. The male G.-M. is entirely of a satiny white colour above; the female yellowish with darker markings;

Ghost-Moth (*Hepialus humuli*):

1, eggs, natural size; 2, the same, magnified; 3, larva or caterpillar; 4, chrysalis; 5, imago or perfect insect, male; 6, the same, female.

both sexes are brown on the under side. They are to be seen flying about in the twilight, generally over lawns and pastures, not unfrequently in churchyards, from which circumstance, and from the white colour of the males and their sudden disappearance in the imperfect light on their folding their wings, or rising above the level of the spectator's eye so that the brown part is turned towards him, they derive their name. The caterpillar is yellowish white, with scattered hairs, sometimes nearly two inches long. It spins a large cylindrical cocoon among the roots on which it has been feeding, and there becomes a chrysalis.

GHOSTS. See APPARITIONS.

GHUMURDJINA, or **KOMULDSINA**, a town of European Turkey, in the eyalet of Rumili, is situated on the right bank of the Karadji, about 80 miles south-west of Adrianople. It has extensive bazaars and a small citadel, and is supposed to contain about 8000 inhabitants.

GHŪR, or **GHORE**, a mountainous district of Western Afghanistan, lying south-east from Herat. It was conquered by the famous Sūnni hero, Mahmūd of Ghizni (q. v.), and about three centuries afterwards was overrun by Genghis Khan, who almost completely exterminated the ancient inhabitants. It is celebrated in history as having been the original possession of the princes who established the second Mohammedan dynasty in Hindūstān. It is inhabited at the present day by the independent nomad Tartar tribes of the *Hasāreh* and *Kimāk*, principally the latter.

GHŪRI, or **SULTANS OF GHŪR**, were a race of princes who had the seat of their empire in the country of GhŪr (q. v.), and ruled over Persia, Northern Hindūstān, and Transoxiana. The first of this family mentioned in history is Sūri, who opposed an obstinate but unavailing resistance to Sultan Mahmūd of Ghizni. One of his descendants, named Husseyna, was subsequently appointed governor of GhŪr, in which office he was

succeeded by his sons. But Behram Shah having put to death one of the brothers, the others threw off their allegiance to the race of Sebekteghin, and hostilities ensued (see GHIZNEVIDES), in which the eldest brother, Seyf-ud-deen, was killed, and his brother Allah-ud-deen, surnamed Jehaun-souz (the Conflagrator), succeeded to the sovereignty. After subduing the sultan of Ghizni, Allah-ud-deen invaded Khorassan, but was defeated and taken prisoner by Sultan Sunjur the Seljuk. He was succeeded by his son Mahommed in 1160, who was assassinated at the end of the first year of his reign. Gheitheddin Mahommed ascended the throne in 1161, and after a long and bloody contest with the Khaurezmians, succeeded in obtaining possession of Khorassan. During his reign the affairs of Ghizni were committed in charge to his brother, Shahab-ud-deen Mahommed, who, having subdued the Ghiznevide provinces west of the Indus, crossed that river and conquered successively the provinces of Multan (1176), Lahore (1186), and Ajmere (1190), defeating the rajah of Ajmere's army numbering 300,000 horse and 3000 elephants, and in the course of the next six years conquering Hindustan as far south as Nagpur, and westward to the Irrawady. It is from this epoch that the preponderance of Islam in Hindustan is dated. Shahab-ud-deen succeeded to the throne in 1203, on the death of his brother (see GHIZNEVIDES). The house of Ghor had now reached its acme of power, their territory extending from the Caspian Sea to the Bay of Bengal, and from the Jihon to the Indian Ocean. Shahab-ud-deen, having invaded Khaurezm in 1204, was attacked by the sultan of that country, and completely routed. In the following year, he undertook an expedition into Kojud, on the south border of Cashmere, in order to reduce that rebellious province, in which undertaking he obtained complete success, but on his return was assassinated by one of the Fedayan, or followers of Hussun Sabah, in 1206. His nephew, Mahmud, succeeded; but after a short reign of four years was assassinated. After his death, some members of the family made feeble efforts to revive the grandeur of their ancestors, but as the sultans of Khaurezm had by this time subjugated the whole Persian empire, their attempts were fruitless.

GIANIBELLI, or GIAMBELLI, FEDERIGO, a famous military engineer, was born at Mantua about the year 1530. After serving for some time in Italy, he proceeded to Spain and offered his services to Philip II.; but having failed to obtain an audience of that monarch, and conceiving, moreover, that he had been personally slighted, he abruptly quitted Madrid, swearing, as the story goes, that the Spaniards would yet hear of him; and after a residence for some time at Antwerp, where he acquired a high reputation as a mechanist, passed over to England and entered the service of Queen Elizabeth, who granted him a pension. During the War of Independence in the Netherlands, Alexander, Duke of Parma, generalissimo of the Spanish forces, besieged Antwerp in 1585, whereupon Elizabeth commissioned G. to proceed to the assistance of the inhabitants. On his arrival, he found that the Spaniards had built a vast bridge across the Scheldt, interrupting all communication with the sea, by which alone the city could get provisions or help. Setting his wits to work, G. invented an infernal machine, which he launched against the bridge one stormy night. The effect was frightful. The whole Spanish army was roused by the noise, and the Scheldt was found to be quivering to its lowest depths. The obstructing bridge was blown into the air, and no less than 800 men—among whom were some of the best Spanish officers—were killed.

Many Spanish ships also were either burned or sunk. The want of unity, however, among the citizens, ultimately rendered G.'s aid unavailing, and he was obliged to return to England. Here he was employed at the time of the threatened Spanish invasion in fortifying the coast-line, which he did in a very skilful manner. When the Armada appeared in the Channel, it was G. who proposed and carried out the plan of sending fire-ships into the midst of the enemy, and in this way greatly contributed to their defeat. After this he disappears from history, and all we know of him is that he died in London.

GIANNO'NE, PIETRO, an eminent historian and lawyer, was born, 1676, at Ischitella, a village of Capitanata, in Naples. He early distinguished himself as an able and learned practitioner at the bar of Naples, and soon realised an easy independence, which enabled him to devote his time and energies to his favourite historical researches. In his beautiful villa, adjoining Naples, he laboured during the space of twenty years at his greatest historical work, which, in 1723, he published in four volumes, under the title of *Storia Civile del Regno di Napoli*. This valuable and comprehensive work, not only treats of the civil history of the kingdom, but also contains learned and critical dissertations on the laws, customs, and administrative vicissitudes of Naples from the most remote times, tracing the successive working of Greek, Roman, and Christian influences on the legislative and social institutions. Some severe strictures on the spirit of worldly aggrandisement, and progressive corruption of the doctrines and practices of primitive Christianity apparent in the modern Roman Catholic Church, so enraged the ecclesiastical party, that G. was universally denounced and anathematised from pulpit and altar. The ignorant fanaticism of the lower classes was aroused by the grossest calumnies levelled at the great writer, who was finally forced to yield before the tempest and take refuge at Vienna. The history was solemnly condemned as heretical and libellous by the pope, and was strictly prohibited. G. was granted a small pension by the Emperor Charles VI., under whose dominion Naples then was, and received, in some degree, compensation for his sufferings, in the admiration and sympathy of the enlightened spirits of his own land. In 1734, G. was deprived of his pension and returned to Venice, from whence he was expelled and forced to seek shelter in Geneva. There he composed his famous and bitterest diatribe, entitled *Il Triregno*, against the papal pretensions, and even proclaimed his adoption of the Calvinistic doctrines. Shortly after, an emissary from the court of Turin, having artfully ingratiated himself into the confidence of G., induced him to enter the Sardinian states, where he was immediately arrested and conducted to the fortress of Turin a close prisoner. G. beguiled his tedious confinement with his chosen studies, and retracted his change of religious opinions, a step which in no way alleviated his persecution. He died a prisoner in the fortress, in 1748, after an incarceration of twelve years. His son, Giovanni, was assigned a liberal pension by the new king of Naples, Don Carlos of Bourbon, who thus sought to avert from his house the reproach which overwhelmed the persecutors and jailers of one of Italy's most illustrious citizens. *La Storia Civile* has passed through several editions, the most modern is that of Milan, 1823, in 13 vols., 8vo. See *Corniani*; *Vita di P. Giannone da Leonardo Panzini*; *Storia della Letteratura Italiana da Maffei*.

GIANTS AND DWARFS. A giant (from the

GIANTS AND DWARFS.

Greek word *gigas*) is an individual whose stature and bulk exceed those of his species or race generally.

Until the beginning of the present century, it was universally believed that giants, of a size far exceeding those who are exhibited in our times, formerly existed, either as nations or as individual specimens. This belief was based (1) on the asserted discovery of colossal human bones; (2) on supposed scriptural evidence; and (3) on the evidence of various ancient and medieval authors.

A reference to the first volume of Cuvier's *Osséments Fossiles* will show that the bones of elephants, rhinoceroses, mastodons, &c., have been exhibited and accepted as evidence of pre-historic giants. Even so good a naturalist as Buffon fell into this popular delusion, and figured the bones of an elephant as the remains of human giants. Isidore Geoffroy Saint-Hilaire, in his *Histoire des Anomalies de l'Organisation*, notices several of the most famous of these cases. A gigantic skeleton which was found at Trapani, in Sicily, in the 14th c., was at once pronounced to be that of the classical giant Polyphemus, and his height was calculated at 200 feet. It was pointed out that the bones differed in form as well as in size from those of man, but this objection was easily met by the question: Why, if his height was sixty times as great as that of an ordinary man, should not his form be also different? Many less celebrated giants were subsequently exhumed in Sicily, and the existence of the 'Osseous Caverns,' described by De Quatrefages in his *Rambles of a Naturalist*, fully accounts for such discoveries, at an epoch when few could recognise the differences in form between the bones of an elephant and those of man. Passing over a giant whose bones were exposed by the action of the Rhone in 1456, and whose height was estimated at 30 feet, and another whose skeleton was discovered near Lucerne in 1577, and who, according to the calculation of the learned physician Plater, did not exceed 19 feet, we come to the case of King Teutobochus, whose remains were discovered near the Rhone in 1613, by a surgeon named Mazurier, whose *Histoire Véroitable du Géant Teutobochus* (1618) gave rise to a warm controversy. The anatomist Riolan endeavoured to expose the imposture, but the Parisians rushed in crowds to see the mastodon's bones, which were reported to have been found in a tomb 30 feet long, bearing the inscription 'Teutobochus Rex.' Nor have our own countrymen been less credulous than their continental neighbours. In 1712, Dr Mather, in the *Philosophical Transactions*, announced the discovery of enormous bones and teeth which had been found in the state of New York, and which he regarded as affording evidence of the existence of giants of enormous size in ancient times. The bones were in reality those of a mastodon.

The Scripture evidence, when carefully examined, does not amount to much. The Hebrew words *nephilim* and *giborim*, which occur several times in the Book of Genesis, and which are translated *giants*, might as well be translated *bearded*, *cruel*, or *violent men*. The height of Og, king of Bashan, is not given; we are only told the length of his bed; and excluding his helmet, which was probably taken into account in the recorded measurement, Goliath, at most, did not exceed eight feet and a half in stature, and consequently was not taller than some giants of modern days.

The classical evidence is abundant, but obviously untrustworthy. Thus Plutarch relates that Serbonius had the grave of Antæus, in the city of Tunga, opened, and 'finding there his body, full 60 cubits long, was infinitely astonished, ordered the tomb to be closed, gave his confirmation to the

story, and added new honours to the memory of the giant.' Pliny reports that an earthquake in Crete disclosed the bones of a giant 46 cubits in length, who was held by some to be Orion, and by others Otus. Descending to more certain evidence, there is no doubt that a height of between 8 and 9 feet, and probably of more than 9 feet, has been attained. There is a skeleton in the Museum of Trinity College, Dublin, 8 feet 6 inches in height; that of O'Brien (or Byrne), in the Museum of the College of Surgeons of England, is 8 feet 2 inches; and that of a giant in the Museum at Bonn is 8 feet; and the actual body with the soft parts attached was probably two or three inches longer than the skeleton. (O'Brien, for example, measured 8 feet 4 inches after his death, as we find recorded in the *Annual Register*, vol. xxvi. p. 209.)

We commonly apply the term *Dwarf* to any organised being, but especially to individuals of the human species, whose height is much less than the average height of their race. Strictly speaking, however, the word should be restricted to those cases in which there is a general and uniform arrest of growth, except, perhaps, in the nervous system, which is often fully developed in dwarfs.

The ancients believed not only in dwarfs of extreme minuteness, but in nations of them. Aristotle, the greatest naturalist that perhaps ever existed, declared that the report of trustworthy witnesses testifies to the existence of a minute race of men, with minute horses, living in the caves which are washed by the waters of the Nile; and Pliny gives various details regarding their habits and their geographical position. Amongst the extreme cases recorded on ancient authority, we may notice that of Philetas, a poet who was a contemporary with Hippocrates, and who was obliged to ballast himself, to avoid being blown away by the wind; that of the Egyptian dwarf mentioned by Nicephorus Callistus, who, at the age of 25 years, did not exceed a partridge in size; and lastly, that of the poet Aristratius, of whom Athenæus records that his stature was so small that no one could see him.

We shall now briefly notice a few of the most remarkable dwarfs of modern times. All the readers of *Peveril of the Peak* are acquainted with Sir Geoffrey Hudson. Up to the age of 30, his height was only 18 inches; from that age, he rapidly grew to the height of 3 feet 9 inches. He had an enormous head, and large hands, but in other respects was well proportioned. He died at the age of 63. Count Joseph Borowlaski was the son of well-formed healthy parents of the ordinary size, who had six children, of whom the first, third, and fifth were dwarfs. Joseph, who wrote a history of his own life, records that his eldest brother was 3 feet 6 inches high; then came a son who was 5 feet 10 inches; then came Joseph himself, whose height at 20 was 2 feet 4 inches, and at 30, 3 feet 3 inches. He was succeeded by three others, the middle one being a girl, who died at 22 of the small-pox, being then 2 feet 2 inches, but of admirable proportions. Joseph Borowlaski was very well proportioned, was married to a woman of ordinary size, who brought him several well-formed children, and died at Bank's Cottage, near Durham, in 1837, at the age of 98—a great age for an ordinary man, and without example in the history of dwarfs. Nicholas Ferry, commonly known under the name of Bêbé, was another celebrated dwarf. His parents and his brothers and sisters were all well-formed persons. He was a seven months' child, and at birth measured less than eight inches, and weighed less than a pound. When five years old, a physician, who examined him, reported that he then weighed

GIANTS AND DWARFS.

9 pounds 7 ounces, and stood 22 inches high, but was formed like a young man of 20. He died in his 23d year, being then under three feet high. (Humphry, *On the Human Skeleton*, p. 101.) In the Museum of the Faculté de Médecine of Paris, there is a wax-model which represents him at the age of 18; and in the Muséum d'Histoire Naturelle is his skeleton, which in the complete ossification of the bones, and in the disappearance of the cranial sutures, resembles that of an aged person. According to C. G. Carus (*Symbolik der menschlichen Gestalt, Zweite Auflage*, 1853, p. 83), General Tom Thumb, the well-known dwarf, exhibited about twelve years ago in this country, was 25 inches in height, and weighed 25 pounds; and Prince Colobri, a Slesvig dwarf, who was being exhibited in Dresden in 1851, was of a similar height and weight, his age being 21 years. Carus likewise examined, in the year 1857, a Dutch dwarf, who took the name of Tom Thumb. He was aged 18 at the time of the examination, and then measured about 2 feet 4 inches. (These are probably Prussian measures, which slightly exceed those of this country.)

On comparing the data in our possession regarding giants and dwarfs—and for most of these data we must refer the reader to Geoffroy Saint-Hilaire's *Histoire des Anomalies*—it appears (1) That giants are of rarer occurrence than dwarfs; (2) That giants are usually of a lymphatic temperament, and of a very delicate complexion, often deformed, and almost always badly proportioned; that their muscles are flabby, and their voice weak; while dwarfs are often perfectly well proportioned, and are strong for their size; (3) That giants are never long-lived—O'Byrne died at 22, Magrath at 20—while dwarfs seem to attain the full ordinary period of human existence—Borowlaski died at 98, Hudson at 63; and although we do not know the age at which Therese Souvray—a dwarf described by Virey—died, we know that at the age of 73 'elle était encore vive, gaie, bien portant, et dansait à la mode de son pays.' (4) That while giants usually exhibit a want of activity and energy, and are feeble both in body and mind, dwarfs are in general lively, active, and irascible (Borowlaski in his memoirs gives a good illustration of the last characteristic, as exhibited by the dwarf Bébé: 'When he perceived that the king took pleasure in my society, he conceived the most violent jealousy and hatred of me . . . and endeavoured to push me on to the fire'; and Sir Geoffrey Hudson's irascibility is well depicted in *Peril of the Peak*). That the intellectual power of dwarfs is sometimes considerable, is sufficiently evidenced in the cases of Borowlaski, General Tom Thumb, and the Dutch Tom Thumb, who, according to Carus, spoke four languages.

We know little of the causes which occasion the excessive development or the arrested growth on which the production of giants and dwarfs depends. Bishop Berkeley* is said to have attempted with considerable success to manufacture a giant. He took a poor orphan, named Magrath, and reared him on certain hygienic principles (Virey conjectures that he fed him with mucilaginous foods and drinks, but nothing seems known on this point), which were so far successful that, at the age of 16, he was 7 feet in height, and that at the time of his death, which occurred, with all the symptoms of old age, at the age of 20, he was 7 feet 8 inches high. If food in this case did really produce a giant, why cannot our farmers be as

successful as the bishop? They can only produce fatty monstrosities, not giants.

Geoffroy Saint-Hilaire devotes a special section of his book to 'the causes of dwarfism,' but he only arrives at the general conclusion, that in these cases there is an obstacle to the proper nutrition and development of the fœtus; that this obstacle may be due either to something wrong in the maternal organism, or more commonly to some disease affecting the fœtus itself; and that this disease is usually rickets or rickets.

Mythological Giants and Dwarfs.—Giants play a part in the mythology of almost all nations of Aryan descent. The Greeks, who represented them as beings of monstrous size, with hideous countenances, and having the tails of dragons, placed their abode in volcanic districts, whether they were fabled to have been banished after their unsuccessful attempt upon heaven, when the gods, with the assistance of Hercules, imprisoned them under Ætna and other volcanoes. Their reputed origin, like the places of their abode, points to the idea of the mysterious electrical and volcanic convulsions of nature, which they obviously typify; and, in accordance with this view, they are said to have been of mingled heavenly and earthly descent, and to have sprung from the blood that fell from the slain Ouranos upon the earth, Ge, which was their mother. In the cosmogony of the northern nations, giants occupy a far more important place than the Greeks assigned to them, for here the first created being was the giant Ymir, called also 'Aurgelmir,' or 'the ancient Chaos,' the progenitor of the Frost-giants (Hrimthursar), among whom dwelt the All-Father before the creation of heaven and earth. The mode of origin of Ymir was as follows: In the beginning of time a world existed in the north, called Nifheim, in which was a well, Hvergelmir, from whence issued a poisonous stream which hardened into ice, the accumulation of which formed the northern part of Ginnungagap, or abyss of abysses, whose southern extremity was radiant with the heat and light which emanated from another world, known as 'Muspelheim.' The meeting of heat and ice produced drops, which, through the agency of the same creative power (the All-Father) which had sent them forth, received life and a human form. This was Ymir, who was nourished from four streams of milk, which flowed from the cow Audhumla, or the nourishing-power, which had been created by Surt, the guardian watch of Muspelheim. While Ymir slept, a man and woman grew from under his left arm, and a son was produced from his feet. In course of time, other beings were generated from the salt and frost-covered stones which the cow Audhumla licked, and from these were born three brothers, Odin, Vili, and Ve, who were gods, and who, having slain Ymir, and dragged him out into the middle of Ginnungagap, formed from his blood the sea and all waters, and from his huge body heaven and earth and all solid things in nature.

With Ymir perished all the frost-giants except Bergelmir, who, with his wife, escaped on a chest or drum, and became the father of the new giant dynasty of the Jötuns. The gods formed, however, of the eyebrows of Ymir, a wall of defence against these giants, who thenceforward dwelt in Jötunheim, beyond the boundaries of the ocean, which encircled Midgard, the future abode of the sons of men. The Æsir or gods lived in their own city, Asgard, occupying themselves with works of industry till they were corrupted by the giantesses who came to them from Jötunheim, when the Golden Age ceased, and discord arose among the gods. At the instigation of the maidens

* Our authority for this statement is Geoffroy Saint-Hilaire, who quotes Watkinson's *Philosophical Survey of Ireland* (Lond. 1777). The bishop died in 1753.

from Jötunheim, the gods created dwarfs and men; the former from the maggots generated within the body of Ymir, and the latter from trees; and from this time the giants gradually lost their power, under the united opposition of gods and men. In the popular belief, common in all countries, that through the agency of giants mountains and islands have arisen, and rocks and mountains have been hurled from their original sites, we trace the ideal personification of the forces of nature, which, after long periods of inert repose, exhibit sudden and uncontrollable outbursts of violence: thus giants were represented as good-humoured and complacent when at rest, but implacable, savage, and treacherous when excited; while they were at all times impressed with a consciousness that, notwithstanding their huge bulk, and the excess of heads and arms with which many of them were gifted, they were but stupid monsters, unable to cope with the ready wit and keen intelligence of divine or even human beings, to whom they believed it was the decree of fate that they must ultimately succumb. In this respect, the giants typify the heathen element in its conflict with Christianity, and northern Sagas are rife with the histories of gigantic, wild, and cruel races, known as *Thursar* (Goth. *thaurjan*, to thirst, or *Jötnar*; Anglo-Saxon *etan*, to eat), who ate and drank voraciously, and subdued all things to their sway, until there came from the far East a people, who knew and worshipped the god of the universe under the name of the 'All-Father,' and who, by their greater skill, overcame the savage giants of the north, and compelled them to withdraw more and more into the recesses of the forests and mountains, whence they only emerged from time to time in the form of mountain trolls and giants.

The dwarfs who figure in the *Eddas* as cunning and crafty elves, skilled in magic and in the working of metals, are conjectured to have been a race of Oriental Lapps, who immigrated into Sweden and Norway later than the Finns, who were the descendants of the giants, and therefore the oldest of the races that now occupy the Scandinavian peninsula. When considered under the broadest signification of the term, dwarfs (Goth. *dvarfs*, which Grimm conjectures may be identical with the Greek *theourgos*, one who does supernatural works) typify the transition from inorganic to organic nature, and thus personify the subordinate powers of nature; and under this idea they are represented as assisting men by combining the primary ores into new mineral bodies, and fostering the development of fruits and seeds. Considered from this point of view, they occupy an intermediate position between giants and men; and while they fear both, they incline to serve the latter at the expense of the former, and thus appear under the form of beneficent elves (q. v.), fairies, and brownies (q. v.). During the latter part of the middle ages, when the traditional folk-lore of Western Europe was being supplanted by the literature of the monks, which consisted mainly of legends of saints, the devil and the fallen angels took the place, in the minds of the illiterate, that had hitherto been occupied by giants and dwarfs; and the various supernatural feats of strength which had in earlier ages been ascribed to these imaginary beings, were attributed to Satan and his attendant spirits, or in some cases to the saints of the church.—See Grimm's *Deutsche Mythologie*, Thorpe's *Northern Mythology*, Grundtvig's *Nordens Mythologie*, and Petersen's *Nordisk Mythologie*.

GIANTS' CAUSEWAY (deriving its name from a mythical legend that it was the commencement of a road to be constructed by giants across

the channel to Scotland), is a sort of pier or mole, of columnar basalt, projecting from the northern coast of Antrim, Ireland, into the North Channel, about 15 miles from Coleraine. It is part of an extensive and overlying mass of basalt, from 300 to 500 feet in thickness, which covers almost the whole county of Antrim and the eastern part of Londonderry, extending over an area of nearly 1200 square miles. The basalt occurs in several beds, interstratified with layers of ash. It covers secondary strata, converting the chalk into granular limestone, and the lias shale into Lydian stone, where it comes in contact with them. Several of the basaltic beds are more or less columnar, but three layers are remarkably so. The first appears at the bold promontory of Fair Head; its columns are coarse and large, exceeding 200 feet in height. The other two are seen together rising above the sea-level at Bengore Head. The lower one forms the Causeway at the place where it is uncovered, as it again gradually dips under the sea. It is exposed for 300 yards, and exhibits an unequal pavement, formed of the tops of polygonal columns, fitting so compactly that the blade of a knife can scarcely be inserted between them. The columns are chiefly hexagonal, though examples may be found with 5, 7, 8, or 9 sides; and there is a single instance of a triangular prism. The diameter of the pillar is very variable, but the average size is from 15 to 20 inches. Each pillar is divided by joints of unequal length, the concave hollow at the end of one division fitting exactly into the convex projection of the other. The rock is compact and homogeneous, and is somewhat sonorous when struck with a hammer.

The Causeway is divided into the Little, Middle, and Large Causeways. The Large Causeway, which is formed by the lowest of the three columnar beds of basalt, is about 30 feet wide, and runs more than 200 yards from its exposure on the cliff till it is covered by the sea. The Little and Middle Causeways are formed from the second columnar stratum, and are less remarkable than the other.

GIAOUR, a Turkish word, corrupted from the Arabic *kiafir* ('unbeliever'), and applied by the Turks to all who reject Mohammedanism, especially to European Christians. Though at first used exclusively as a term of reproach, its signification has been since modified, and now it is frequently employed merely as a distinctive epithet. Sultan Mahmud II. forbade his subjects to apply the term *G.* to any European.—*G.* was the title of a poem written by Lord Byron, and published in 1813. Compare with *G.* the word Guebres (q. v.).

GIAVENO, a town of Piedmont, stands on the left bank of the torrent Sangone, 17 miles west-south-west of Turin. It is surrounded by walls, and possesses a castle, erected in 1369 by the abbot of the monastery St Michel della Chiesa. In 1003, Urban II., Count of Savoy, endowed this abbey with the lands of *G.*, which, however, owing to the unproductiveness of the soil, were not of great value. The town was formerly a thriving commercial place, with a considerable trade in linen, leather, &c. It still possesses some manufactories of linen, cotton and silk stuffs, besides tanneries and iron forges. Pop. 9144.

GIBBET. See HANGING.

GIBBON, EDWARD, the historian of *The Decline and Fall of the Roman Empire*, was born at Putney, on the 27th April (O. S.) 1737, and was the first child of Edward Gibbon and of Judith Porten, both of good family, and the only one of seven children that survived infancy. Memoirs of his *Life and Writings* were written by himself, and these, with

his letters and other miscellaneous works, were published after his death by his friend Lord Sheffield, with whom he had long carried on a most confidential correspondence. Few autobiographies are so interesting as that of G., and none more veracious. It is a self-portraiture, both in regard to what is said and in regard to the manner in which it is said—his pride, self-complacency, integrity, and contempt for the contemptible, and much beside, being all clearly revealed as proposed by him with 'truth, naked unblushing truth.' He reflects: 'My name may hereafter be placed among the thousand articles of a *Biographia Britannica*; and I must be conscious that no one is so well qualified as myself to describe the series of my thoughts and actions.' So, in his 52d year, after he had finished his 'arduous and successful work,' he proceeded to do it. Like most thinkers, his actions were few, and apart from his thoughts and the growth of his mind quite unimportant. He spent a sickly childhood in occasional lessons and desultory reading and discussion with his mother's sister, a lady of a strong understanding and warm heart, whom he calls 'the mother of his mind,' and to whose kindness he ascribes not only the bringing out of his intellectual faculties, but the preservation of his life in these critical early years. One of his temporary masters was the Rev. Philip Francis, the translator of Horace. His father, who seems to have been the somewhat impulsive possessor of the wreck of a fortune, had him entered at Magdalen College, Oxford, at the age of 15, when he was very imperfectly prepared for this crisis; his extensive reading and interrupted education having produced 'a stock of erudition that might have puzzled a doctor, and a degree of ignorance of which a school-boy would have been ashamed.' Here he spent 14 idle months, the chief result of which was, that in his incursions into controversial theology he became a convert to the Church of Rome, and found himself shut out from Oxford. He was by his father placed under the care of Mallet the poet, and a deist, but by his philosophy the young enthusiast was 'rather scandalised than reclaimed.' To effect his cure from popery, he was sent to Lausanne, in Switzerland, to board in the house of M. Pavillard, a Calvinist minister, a poor but sensible and intelligent man, who judiciously suggested books and arguments to his young charge, and had the satisfaction of seeing him reconverted to Protestantism, in witness of which conversion he received the sacrament in the church of Lausanne on Christmas-day 1754, his belief in popery having lasted not quite 18 months. He lived nearly five years in this house, respecting the minister, and enduring with more or less equanimity the 'uncleanly avarice' of his wife; and it was here that he began, and carried out steadily and joyously to an extent that will astonish very hard students, those private studies which, aided by his enormous memory, made him a master of erudition without a superior, and with hardly an equal. Here also he fell in love with Mademoiselle Susan Curchod, the daughter of a clergyman, a young lady beautiful and learned, who afterwards became the wife of M. Necker, the distinguished French minister and financier. G.'s father disapproved of this alliance, and he yielded to his fate. After his return to England and his father's house, he persevered in his studies as he best could.

He finished a little work in French, begun at Lausanne, and published it under the title of *Essai sur l'Étude de la Littérature* in 1761. In the same year he became captain in the Hampshire militia, in which he continued for two and a half years. Of this part of his career he observes: 'The discipline and evolutions of a modern battalion gave me a

clearer notion of the phalanx and the legion; and the captain of the Hampshire grenadiers (the reader may smile) has not been useless to the historian of the Roman Empire.' The militia being disbanded, he revisited the continent, and travelled into Italy; and among the benefits of foreign travel, he notes its influence in suggesting the work of his life in these words: 'It was at Rome, on the 15th of October 1764, as I sat musing amidst the ruins of the Capitol, while the barefooted friars were singing vespers in the temple of Jupiter, that the idea of writing the decline and fall of the city first started into my mind.' His plan, originally circumscribed to the decay of the city, grew by years of reading and reflection and delay to embrace the empire. During these years his father died, leaving his affairs deranged, and he entered parliament for the borough of Liskeard at the beginning of the struggle with America, 'and supported with many a sincere and silent vote the rights, though not, perhaps, the interest, of the mother-country.' He sat eight years, but never had courage to speak; 'the great speakers filled him with despair, the bad ones with terror.' In 1776, the first volume of *The Decline and Fall* was published, and its success was prodigious. The reputation of the author was established before the religious world had had time to consider and attack the last chapters of the work—the 15th and 16th—in which, while admitting, or, at least, not denying, the 'convincing evidence of the doctrine itself, and the ruling providence of its great author,' he proceeds to account for the rapid growth of the early Christian church by 'secondary' or human causes. Hume, who was then slowly dying, in a highly complimentary letter, told him in regard to these chapters: 'I think you have observed a very prudent temperament; but it was impossible to treat the subject so as not to give grounds of suspicion against you, and you may expect that a clamour will arise.' The prophetic criticism was correct; the grounds of the 'clamour' being, at the best, only strong suspicions that, in becoming a convert from Popery to Protestantism, Gibbon had, like Bayle, gone on 'to protest against all sects and systems whatsoever.' That he did not like to see the barefooted friars in the temple of Jupiter is clear enough all through the six large and compact volumes of his history. He finished this great work on the 27th June 1787 at Lausanne, to which he had retired for quiet and economy after leaving parliament, and holding office under government for a short time. In his *Memoirs*, he tells the hour of his release from his protracted labours—between eleven o'clock and midnight—and records his first emotions of joy on the recovery of his freedom and the sober melancholy that succeeded it, all in a style and in a connection which, with much beside, must be studied in his own pages by those who would know Gibbon in his real greatness, self-complacency, egotism, and contemplative sadness. The lady of Lord Sheffield, his close friend, having died, G. left Lausanne for England to console him; and about six months after his arrival, he died without apprehension or suffering, on the 16th January 1794, in St James's Street, London, of an enormous rupture and hydrocele, which, as it gave him no pain, he had allowed to grow neglected without speaking of it to either friend or physician for thirty-two years.

In person, G. became very corpulent, and the small bones of the big-headed delicate boy were in after years hardly adequate to sustain their load. Vanity was, perhaps, his only frailty. He affected the manners of the fine gentleman of last century to the end, and they adjusted themselves grotesquely to the unwieldy body and the massive mind.

It is not easy to characterise a man of so gigantic and cultivated an intellect in few or many phrases. He was a faithful friend, pleasant and hardly rivalled in conversation, not disliked by any one who came near him. His *Decline and Fall* is probably the greatest achievement of human thought and erudition in the department of history; at least Niebuhr gives it this high praise. It is virtually a history of the civilised world for thirteen centuries, during which paganism was breaking down and Christianity was superseding it; and thus bridges over the chasm between the old world and the new. Its style is marked by the highest power of condensation, and is full of smiting phrases and ponderous antithesis. Byron designates him

'The lord of irony, that master-spell.'

He himself was not unaware of this part of his genius, and he says he cultivated it by reading the *Provincial Letters* of Pascal every year; which must have become eventually a mere form, for two careful readings sufficed to fix almost any composition indelibly on his impressible and retentive memory. His accuracy in regard to fact has never been successfully impeached, and his industry has never been questioned. The best edition of *The Decline and Fall* is that published by Dr W. Smith in 1854-1855, containing the notes, comments, and corrections of Guizot, Wenck, and Dean Milman.

GIBBON (*Hyllobates*), a genus of apes, or tailless monkeys, natives of the East Indies. They are nearly allied to the orangs and chimpanzees, but are of more slender form, and their arms so long as almost to reach the ground when they are placed in an erect posture; there are also naked callosities on the buttocks. The canine teeth are long. The gibbons are inhabitants of forests, their long arms enabling them to swing themselves from bough to bough, which they do to wonderful distances, and with extreme agility. They cannot, however, move with ease or rapidity on the ground. The conformation of the hinder extremities adds to their difficulty in this, whilst it increases their adaptation to a life among the branches of trees, the soles of the feet being much turned inwards. None of the gibbons are of large size. The COMMON G., or LAR G. (*H. lar*)—black, with a border of gray hair

gray, and the four hands white—is a native of Sumatra. The ACTIVE G. (*H. agilis*), found in Sumatra, is particularly remarkable for the power which it displays of flinging itself from one tree to another, clearing at once, it is said, a distance of forty feet. The WOW-WOW (*H. leuciscus*) is a G. found in Malacca and the Sunda Isles. The HOOLOCK (*H. Hoolock*) is a native of the Garro Hills. The SIAMANG (*H. syndactyla*), a Sumatran species, differs from the rest of the genus in having the first and second fingers of the hinder extremities united to the second joint. All the gibbons are of gentle disposition, and easily domesticated.

GIBBONS, ORLANDO, an eminent English musician, was born at Cambridge in 1583. At the age of 21, he became organist of the Chapel Royal; and in 1622, on the recommendation of the learned Camden, he received from Oxford University the degree of doctor in music. He was the best church composer, and, according to Anthony Wood, 'one of the rarest musicians of his time.' His madrigals have always been popular. Of these, three, *Dainty Sweet Bird*, *O that the Learned Poets*, and *The Silver Swan*, are considered far superior to most compositions of the kind. He composed the music for the marriage-ceremonial of Charles I., in 1625; but while attending it officially, he caught the small-pox, and died at Whitsunday thereafter. A monument to his memory, erected by his wife over his burial-place in Canterbury Cathedral, is still shewn. His anthems, *Hosannah to the Son of David! Almighty and Everlasting God!* and *O Clap your Hands together!* are reckoned by Wood 'master-pieces of the most ingenious and scientific writing in fugue that musical skill ever brought forth.' His two brothers, Edward, organist of Bristol, and Ellis, organist of Salisbury, were likewise good musicians. Edward, sworn in a gentleman of the Chapel Royal in 1604, was master to the famous composer Matthew Lock. During the civil wars he lent Charles I. £1000, for which he was afterwards deprived of a considerable estate, and, with his three grandchildren, thrust out of his house at a very advanced age. In the *Triumphs of Oriana* are two madrigals by Ellis Gibbons. G.'s son, Dr Christopher Gibbons, at the Restoration, was appointed principal organist to the king and to Westminster Abbey, and by a recommendatory letter from Charles II. was created doctor in music by the university of Oxford. Celebrated for his organ blowing, he is said to have been the instructor on that instrument of Dr John Blow, the well-known composer of the pieces published under the title of *Amphion Anglicus*, who died in 1708.

GIBBONS, GADLING, an eminent English sculptor and wood carver, of Dutch extraction, was born in London in 1648. On the recommendation of Evelyn, he was, by Charles II., appointed to a place in the Board of Works, and employed in the ornamental carving of the choir of the chapel at Windsor. His works display great taste and delicacy of finish, and his flowers and foliage have almost the lightness of nature. For the choir of St Paul's, London, he executed the foliage and festoons, and those in lime-tree which decorate the side-aisles. At Chatsworth, the seat of the Duke of Devonshire; at Burleigh; at Southwick, Hampshire; and other mansions of the English nobility, he executed an immense quantity of carved embellishment. At Petworth, he devised the ceiling for a room, which is believed to be his *chef-d'œuvre*. In marble and bronze, he also produced several fine pieces. Among these are the statue of James II., behind the Banqueting Hall,

White-handed Gibbon (*Hyllobates albimanus*).

around the face—is found in some parts of India, and in more eastern regions. The WHITE-HANDED G. (*H. albimanus*)—black, the face bordered with

Whitehall; of Charles I., at Charing Cross; and that of Charles II., at the Bank of England. The wooden throne at Canterbury; the monument of Viscount Camden at Exton, Rutlandshire; and the baptismal font at St James's Church, London, are by him. He died August 3, 1721.

GIBBOSITY (Lat. *gibbus*, Gr. *húbos*, *kuphos*, humpbacked), a state of disease characterised by protuberance of a part of the body; chiefly applied to humpback or other distortions depending on disease (Rickets, q. v.) of the spinal column.

GIBBOUS, a term signifying 'protuberant,' 'swelling out,' applied to bodies which are double-convex, and particularly to the moon, when she is within a week of the full.

GIBBEAH, a Hebrew word signifying a 'hill,' and giving name to several towns and places in Ancient Palestine. The only one requiring special mention is *Gibeah-of-Benjamin*, a small city about four miles north of Jerusalem. It was the scene of the horrible story of the Levite and his concubine, related in the 19th chapter of Judges, and subsequently the residence, if not the birthplace of King Saul. Gibeah-of-Benjamin has been identified with the modern village of *Tulci d-Fal*.

GIBEL (*Cyprinus gibelio*), a fish of the same genus with the carp, but of the division of the genus destitute of barbules at the mouth, by which it is easily distinguished from the carp, whilst from the crucian it is at once distinguished by its forked tail. The weight is seldom much more than half a pound, although specimens have been caught of two pounds weight. The G. is common in some parts of continental Europe; it is supposed to have been introduced into England from Germany, but is now fully naturalised in ponds near London and in many other parts of the country. It is generally known in England as the Prussian carp. It is a good fish for the table, but affords little sport to the angler, seldom taking any bait readily. It feeds partly on aquatic plants, partly on worms and molluscs. It is very tenacious of life out of the water, and has been known to recover after thirty hours.

GIBELLINA, a village of Sicily, in the province of Trapani, and 34 miles south-east of the town of that name, is situated amid mountains, has a castle, and a pop. of about 5000.

GIBEON (Heb. signifies 'belonging to a hill'), a celebrated city of ancient Palestine, about 5 miles north-west of Jerusalem. At the conquest of Canaan by the Israelites under Joshua, it was inhabited by the Hivites. By a clever stratagem, the Gibeonites insured the alliance and protection of the invaders, and so escaped the fate of Jericho and Ai; but their deceit being afterwards found out, they were reduced to a condition of servitude, being appointed 'hewers of wood and drawers of water unto all the congregation.' When the five kings of the Amorites besieged G., on the ground of its having entered into a traitorous compact with the common enemy of all the Canaanites, Joshua hastened to its help, and overthrew the besiegers with great slaughter. The battle was attended, we are informed, with supernatural phenomena—viz., the standing still of the sun upon Gibeon, and of the moon in the valley of Ajalon; but as the passage where this occurs (Joshua x. 13) is immediately followed by these words: 'Is not this written in the book of Jasher?' it has been thought that it may perhaps be only an extract from that collection of national songs; and the fact of its forming two hemistichs, while the rest of the narrative is in prose, certainly does not weaken

the probability of this theory. If such a supposition be adopted, the necessity for accepting the statement literally is done away with, and the supposed miracle is resolved into a hyperbole of oriental poetry. The city of G. is mentioned various times in the history of David and his captains; but its sanctity, in the eyes of the Jews, arose from the circumstance of it—or the hill near it—having been for a time the seat of the tabernacle of the congregation, and the brazen altar of burnt-offering. It was at the horns of this altar that the ruthless Joab was slain by Benaiah, the son of Jehoiada; and here Solomon, in the beginning of his reign, with magnificent ceremony sacrificed a thousand burnt-offerings.

GIBRA'LTAR, a rocky promontory, 3 miles in length and $\frac{1}{2}$ mile in average breadth, forms the southern extremity of Spain. It is situated at the extremity of a low peninsula, which connects it on the north with Andalusia; its most southern headland, Point Europa, is in lat. 36° 2' 30" N., and long. 5° 15' 12" W. Five and a half miles distant across the sea is the Spanish town of Algeiras, between which and G. lies the Bay of Gibraltar, called also the Bay of Algeiras. On the east side of this bay is the town of G., inhabited by a motley population of from 15,000 to 20,000 English, Spaniards, Jews, and Moors.

The strip of peninsula connecting G. with the Spanish territory is called the 'neutral ground.' It is so low, that, seen from the sea but a few miles off, G. has the appearance of a detached rock. The approaches both from this neutral ground and from the sea are guarded by a great number of very powerful batteries, and by fortifications so strong in themselves and in their relative bearing on each other, that the rock may fairly be regarded as impregnable so long as a sufficient garrison remains for its defence, and sufficient provision for the maintenance of the troops and any civil inhabitants suffered to reside there during hostilities. The rock is composed of gray primary marble, deposited in strata from 20 to 40 feet thick. The surface near the sea is sandy and red in appearance; higher up, the rock is covered only with short and scanty grass or moss. Seen from the sea, its aspect is uninviting, the whole appearing denuded of trees and verdure: nevertheless, there are grassy, wooded glens in the nooks of the mountain. In the crevices of the rock grow asparagus, capers, palmitas, aloes, and cacti, while the fauna disporting on the wild, rarely trodden upper portions, comprises rabbits, partridges, pigeons, woodcocks, and fawn-coloured Barbary apes. For various military reasons, shooting is discouraged, and these animals therefore enjoy the utmost impunity. The rock, at its highest point, the Sugar Loaf, attains an elevation of 1439 feet above the sea. It is perforated by numerous caverns, the largest of which, called the 'Halls of St Michael,' have an entrance about 1000 feet above the sea. Thence there is a descent through a succession of caves—some ample chambers, others mere passages, through which it is barely possible to creep—to a depth of 500 feet below the entrance: at this point foul air has barred further ingress; but the roaring of the sea has been distinctly heard, which leads to the inference that these gloomy hollows have communication with the waves beneath. Large stalactites are found in most of the caverns, and interesting fossils abound throughout the peninsula.

The climate of G. is, as a rule, healthy, although the period from July to November, when the greatest heat prevails, is attended with some risk to Englishmen: there is, however, a remarkable exception in the case of infants at the period of teeth-cutting, to whom the atmosphere of the place is peculiarly

GIBRALTAR.

fatal. Of late years, the energetic measures adopted by the engineer-officers to improve the drainage of the town have, coupled with stringent police regulations, greatly diminished the death-rate; and G. is as remarkable now for its cleanly appearance as, up to 1814, it was celebrated for being one of the dirtiest towns in Europe. The place is, however, subject to a periodical visitation, once in twelve years, or thereabout, called the G. fever, an epidemic which works sad havoc among the troops.

There are no springs of fresh water on the rock, and the inhabitants are therefore compelled to depend on the rain-fall. In consequence of this, every precaution is adopted to preserve as much of the water as possible; tanks are fed systematically by the drops collected from private roofs, and conduits are made to guide the drainage from the rock surface into great public reservoirs. Among the latter, the Navy Tank, for the supply of ships coming to the port, is conspicuous, its

capacity being from 9000 to 11,000 tons of water. Large stores of grain are maintained in case of siege; but the peninsula does not produce sufficient food to furnish current sustenance for its population. Provisions in plenty can, however, be procured at a cheap rate from the opposite African shore.

The Bay of Algesiras or Gibraltar, is about 8 miles long by 5 broad, with a depth in the centre of upwards of 100 fathoms. The anchorage, however, is not very good, and the bay is quite exposed, especially to the south-west winds, which sometimes drag the ships from their anchors and drive them ashore.

G. has been known in history from a very early period. The Phœnician navigators called it *Atube*, which the Greeks corrupted into *Calpe*, its classical name. With Abyla (now Ceuta) opposite, it formed the Pillars of Hercules, long held to be the western boundary of the world. It is impossible to doubt

Rock of Gibraltar.

that such leaders as Hannibal and his fellow-Carthaginians must have been awake to the importance of this rock in their expeditions from Africa into Spain; but we have no certain information of its natural strength being made available for defensive or aggressive purposes until the year 711 A.D., when the Saracens, passing into Spain under Tarif ebn Zarcas, a general of the Calif Al Walid, for the conquest of the Visigothic kingdom, fortified it, as a base of operations, and a ready point of access from the Barbary coast. From this chieftain it took the name of Gebel-Tarif, or Hill of Tarif, of which Gibraltar is a corruption. One of the old towers of this early castle still remains. Subsequently, G. shared in the revolutions among the Moors of Spain, being now in the hands of Almoravide princes from Africa, and again in the power of native Arab monarchs. In 1309, after a gallant defence, it succumbed to the Christians of Castile under Don Antonio de Guzman. The king of Castile immediately constructed additional works and a dock-yard at the 'Old Mole,' and also took measures to induce a Christian population to settle in the town. The Moors besieged G. in 1315 ineffectually, but in 1333 it fell to the army of the king of Fez, whom a siege by the Castilian monarch failed to dislodge. In 1436,

the Spaniards tried once more to take the stronghold; but they were unsuccessful, until, in a subsequent siege in 1462, the place was captured through the treachery of a renegade Moor. From this time the Moorish power was too thoroughly broken for any serious attempt to be made for the recovery of G., which remained in the hands of the Spanish, and was so strengthened by additional fortifications, that the engineers of the 17th c. accounted it impregnable. A combined Dutch and English force, however, under Sir George Rooke and the Prince of Hesse Darmstadt, demonstrated that G. could be taken; for in 1704, after a vigorous bombardment, and a landing in force, the governor deemed it wise to capitulate. How great, even then, were the capabilities of the rock for defence is seen from the fact that the garrison, only 150 strong, placed 276 of the English *hors-de-combat* before they surrendered.

Since 1704, G. has remained continuously in the possession of the British, but not without the necessity of their resisting many desperate efforts on the part of Spain and France to dislodge them. Before the victors had been able to add to the defences, their mettle was severely tried by a siege in 1704-1705. In 1720, it was threatened, and in 1727 actually attacked by an overwhelming force under the Count

de las Torres. During this siege, the place was near falling into the hands of the assailants. The most memorable, however, of the sieges to which G. has been exposed, commenced in 1779, when Britain, being engaged in the struggle with its revolted colonies, and at the same time at war with France, Spain took the opportunity of joining the coalition, and directed her whole strength against the isolated garrison of this small but redoubtable fortress.

The communications with Spain were closed on the 21st June 1779, and a strict blockade established by the Spanish fleet; the strength of the besieged force being at this period 5382 men, including 1095 Hanoverians, under General Elliott, the governor. Famine speedily set in; the enemy pushed forward his works for the future bombardment, and commenced active annoyance on the 12th January 1780, by firing several shots into the town. Five days later, Admiral Rodney overcame the Spanish admiral, threw a good supply of provisions into the fortress, added 1000 men to the garrison, and, removing all useless mouths, left it dependent on its own strength. During 1780 little of importance happened; scurvy disabled many of the defenders; the besiegers advanced their works, continually increased their force, and by obtaining possession of the opposite African ports, cut off the last chance of provisions being obtained for the stronghold.

In April 1781, starvation stared the British in the face, when, on the 12th, Admiral Darby convoyed 100 merchant-vessels into the bay. The Spaniards instantly opened their fire, hoping to reduce the debilitated garrison before effectual aid was received. 114 pieces of artillery, including 50 13-inch mortars, poured their deadly missiles into the place: for many days this bombardment lasted with unabated vigour, and, though less incessant, it continued without intermission until the 26th November, when, in a desperate midnight sally, the British succeeded in destroying the more advanced of the enemy's lines, in setting fire to many of his batteries, and in blowing up his principal depot of ammunition. This daring enterprise, successfully carried out against lines mounting 135 guns, was attended with surprisingly small loss, and forms one of the most brilliant incidents in a magnificent defence.

After this repulse, the Spaniards ceased severe hostilities for several days, up to which cessation the garrison had been incessantly bombarded for nearly eight months, and had had 568 officers and men placed *hors-de-combat*. The siege continued, however, throughout the winter and spring of 1782 without any remarkable incident. In July, the Duc de Crillon took command of the assailants, and preparations were made for the grand assault. Additional batteries were constructed on the land-side, and floating batteries built for this special siege to batter the fortress from the sea. The latter consisted of ten large vessels, whose sides were fortified by seven feet of timber and other materials supposed to be obstructive of shot; they were covered by slanting shot-proof roofs, and were intended to be moored by massive chains within half-range of the rock. Covered boats, destined to disembark 40,000 troops, were at the same time prepared. The effective force with which General Elliott had to withstand these efforts comprised, with the marine brigade, about 7000 men.

The great attack commenced on the 8th September by a bombardment simultaneously on all sides; 9 line-of-battle ships poured in their broadsides; 15 gun and mortar boats approached the town; while, from the Spanish lines, 170 pieces of ordnance of large calibre opened in one magnificent discharge.

This terrific fire continued till the 12th; when the combined French and Spanish fleets, numbering 47 sail of the line, the 10 battering ships mentioned above, esteemed indestructible, with many frigates and smaller vessels, anchored in the Bay of Algeiras. On the 13th every gun of besiegers and besieged was in play. The battering vessels proved, as anticipated, invulnerable to shot and shell. At noon the enemy depressed their guns and did much damage; and the defenders then resorted to the expedient of red-hot balls. These, with carcasses, and incendiary shells, were concentrated on the battering ships in unceasing volleys. Success was doubtful for some hours, but towards evening the gigantic efforts of the British force began to produce fruit. The ship of the Spanish admiral was in flames, the second in command was soon no better off, and although by eight o'clock the attacking squadron was completely silenced, the fire of red-hot shot was continued without intermission till morning. By 4 A.M. on the 14th, eight of the battering ships were on fire. In short, of the ten invincible batteries, every one was finally burned; the Spaniards lost at least 2000 in killed alone; and the naval attack was completely repulsed with a loss to the heroic garrison of only 16 killed and 63 wounded. It is worthy of record, that notwithstanding the fury to which the British soldiers were wrought, Brigadier Curtis, with a devoted band, made gallant and successful efforts to preserve the poor fellows who were left by their affrighted comrades to perish in the burning hulks.

The great bombardment of the 13th September 1782, was the crowning triumph of the siege; but the firing continued in a harassing degree from the Spanish lines, until the 2d February 1783, when the Duc de Crillon, as much to his own as to General Elliott's satisfaction, announced the conclusion of peace. The Spaniards welcomed their late enemies with the enthusiasm due to heroes. The thanks of parliament were cordially awarded to the gallant band; while brave General Elliott received the decoration of the Bath, and subsequently the title of Lord Heathfield. More space has been allowed to the description of this memorable struggle than we can ordinarily spare to specific wars; but the glorious place it occupies in British annals, the length to which it extended (3 years, 7 months, and 12 days), the disparity of force, the brilliant defence, and the comparatively small loss of the garrison—333 killed, 536 died of disease, 1008 wounded, and 43 deserted—seem to point to this the last siege of G. as an exploit not to be passed over by a mere reference.

Since 1783, the British possession of G. has been unmolested, and few events have happened of any interest, apart from the general history of the empire. At present, England guards this formidable rock with jealous care; every available point for defence bristles with artillery; the mountain is honey-combed with galleries and bomb-proofs, steep escarpes bar all approach, and batteries hewn in the solid stone, frown alike on friend and foe. Immense stores of provision, water, and munitions of war are constantly maintained; and the whole is garrisoned by a thoroughly efficient force of about 5000 infantry, with 1000 artillery, and a smaller body of engineers. The jealousy for its safety would appear to rest rather on making its preservation to the crown of England a point of honour than a matter of national importance; for beyond being a standing menace to Spain, and a source of constant irritation, it is difficult to see its actual use to Great Britain. The harbour is not of great value, and the fortress by no means commands the strait.

With regard to the internal organisation of G.,

the law of England prevails; the governor's decision being final in civil cases not involving more than £300. In more important causes, an appeal lies to the British Privy Council. There is a good police force, under a police magistrate, and tolerable order usually prevails. All religions enjoy a perfect toleration; the Catholics are most numerous, having a bishop and a cathedral; next the Jews, who possess four synagogues; the Protestants, though less numerous, have also a bishop. There are three good public libraries; the best and oldest being that started by the famous Colonel Drinkwater, the historian of the great siege.

G. is a free port, and a resort in consequence of Spanish smugglers, who drive an amazing trade by introducing contraband goods into Spain. The British government is not altogether free from a charge of breach of faith, in the toleration it has given to these dishonest men; for it is bound by many engagements to use its best exertions to prevent any fraud on the Spanish revenues, in consequence of its possession of this peninsula. The colony of G. was for many years a most costly one; but of late, by judicious management, it has been made to defray the expenses of its civil government; the heavy charge for the military force being, of course, payable out of imperial funds. The revenue amounts to about £30,000, and is derived from customs, port and quarantine dues, land revenues, stamps, and licences. Its cost to this country over and above the revenue collected, is computed for the year 1862—1863 to be £300,000.

The town of G. consists of three parallel streets, in which the curious intermingling of English architecture with the Spanish houses spoils the effect of the whole. English domestic building is eminently unsuited to a climate light and hot, like Gibraltar. There are, nevertheless, some handsome structures.

GIBRALTAR, STRAITS OF (anciently the *Straits of Hercules*), extend from Cape Spartel to Cape Ceuta on the African coast, and from Cape Trafalgar to Europa Point on the coast of Spain. The Straits narrow toward the east, their width between Europa Point and Cape Ceuta being only 15 miles, while at the western extremity it is 24 miles. The length (from east to west) is about 36 miles. The tide at Tarifa rises from 7 to 8 feet. Through these Straits a continual current runs from the Atlantic, and is so strong that sailing vessels bound westward can pass only by the aid of a brisk wind from the Levant. It is supposed that the waters of the Mediterranean find an outlet here by an under-current, as well as by the currents which flow westward along the European and African shores respectively.

GIBSON, JOHN, one of the first sculptors of the day, was born at Conway, in North Wales, in 1791. His father, a landscape-gardener, removed to Liverpool about the beginning of this century, and here G. received his education. His love of art manifested itself strongly, even while he was a mere boy at school, and at the age of 16 he entered the marble works of the Messrs Francis, by whom he was introduced to Roscoe, whose art-treasures were placed at his service. Through the kindness of some wealthy friends he was enabled, in his 26th year, to proceed to Rome, where he became a pupil of Canova, and after his death of Thorwaldsen. G. has fixed his residence in that city, and has very seldom revisited his native country. His first reappearance in England was after a lapse of 28 years. At first, G. shewed himself, naturally enough, a faithful follower of Canova, whose graceful softness he made his own. But he did not stop there. By the study of

the antique, which Thorwaldsen was the very man to stimulate, G. finally rose to ideal purity, and a thorough realisation of the grace of form. This advance is clearly traceable in his works. His first important work was a 'Nymph unfastening her Sandal.' This was followed by a group representing 'Psyche borne by the Zephyrs,' which he executed for Sir George Beaumont, and which he has several times repeated. In the church of St Nicholas, in Liverpool, there is a bas-relief of G.'s representing a traveller conducted on the dangerous path of life by his guardian angel. Among his greatest works are his 'Aurora rising from the Waves to announce the Day' (belonging to Lord Townshend); 'The Wounded Amazon' (the property of the Marquis of Westminster); 'The Hunter and his Dog'; 'Narcissus,' 'Helen,' 'Sappho,' 'Proserpine,' and 'Venus.' A spirit of the finest poetry breathes through these works:—they are thoroughly classical, and are marked by a refined and noble severity. His grand innovation, however, viz., that of tinting his figures—though he defends the practice by a reference to Grecian precedents—has excited much keen controversy, and cannot yet be said to have commended itself to the public taste. Among his portrait-statues, those of Huskisson and Peel, George Stephenson, and Queen Victoria, are the best. G. was elected a member of the Royal Academy in 1836.

GIBSON, THOMAS MILNER, the RIGHT HON., politician and statesman, only son of Major Milner-Gibson, was born at Trinidad, 1807, and educated at Trinity College, Cambridge, where he took a wrangler's degree in 1830. He entered parliament as M.P. for Ipswich in 1837, on the Conservative interest. As his political views expanded, he threw off his allegiance to Sir Robert Peel, for which he paid the penalty of the loss of his seat in 1839. In this year he assumed the name of Milner, by royal licence. His eloquence, ability, and superiority to party-ties having gained for him the confidence of the Liberals, in 1841 he successfully contested Manchester against the Conservative candidate, Sir G. Murray. He had previously distinguished himself by his advocacy of free-trade; and during the succeeding five years, occupied a prominent position, both in and out of parliament, among the orators of the League. When the measure for the repeal of the Corn Laws was carried, and the Whigs came into office in July 1846, he was made a privy councillor, and vice-president of the Board of Trade; but, in April 1848, gave up a post which was by no means commensurate with his powers and pretensions. More and more identifying himself with the opinions held by Messrs Cobden and Bright, when the war with Russia broke out, he espoused the unpopular doctrines held by what was called the 'Manchester school,' or as it was otherwise designated, the 'Peace party.' In 1857, the Whigs and Conservatives of Manchester successfully united to unseat him and his colleague, Mr Bright. Milner-G. was, however, returned at the end of 1857 for the borough of Ashton-under-Lyne, which he has continued to represent. In 1858, he moved an amendment to the second reading of the Conspiracy Bill, expressing the abhorrence of the House at the attempt by Orsini upon the life of Napoleon III., and its readiness to amend defects in the criminal law; but censuring the government for not replying to Count Persigny's despatch of January 20, 1858. The amendment was carried, and the government of Lord Palmerston was shattered to pieces. When that noble lord again took office next year, he recognised the skilful parliamentary-tactics and influence of Milner-G., by offering him a place in his cabinet. He became *ad-interim* president of the

Poor-law Commission in June 1859, and President of the Board of Trade next month. The duties of this office he still (1862) efficiently discharges. Milner-G. will be honourably and gratefully remembered for his strenuous advocacy of the abolition of the taxes on knowledge. He was for twelve years president of the association for the repeal of these taxes. His labours were crowned with success, first by the repeal of the advertisement duty in 1853, and secondly, by the repeal of the compulsory stamp on newspapers in 1855. There then only remained the paper duty. Milner-G. had made several attempts in previous sessions to induce successive chancellors of the Exchequer to abolish this impost; and in 1858, he carried a resolution, 'that the maintenance of the excise on paper, as a permanent source of revenue, would be impolitic.' Mr Disraeli, then Chancellor of the Exchequer, consented to accept this motion, but held himself at liberty, with his party, to oppose the Paper Duty Abolition Bill proposed by the government, of which Milner-G. was a member, in 1860. The bill was thrown out by the House of Lords on financial grounds, but was, next session, incorporated into the general financial scheme of the year: and on the 1st of October 1861, the paper duty ceased to exist. Milner-G. has since received a valuable and gratifying commemorative presentation of plate from the members and friends of the Association for the Repeal of the Taxes of Knowledge. This testimonial was presented to the right honourable gentleman at a public banquet in London, in the early part of the present year (1862).

GIDDINESS. See VERTIGO.

GIDEON (Heb. signifies 'a hewer' or 'cutter down', i. e., 'a brave soldier') was the name of the greatest of all the judges of Israel. He was the youngest son of Joash the Abiezrite, and lived with his father at Ophrah, in Manasseh. The period in which his youth was cast was a gloomy one for Israel. The people had fallen into idolatry, and as a punishment 'the Lord had delivered them into the hand of Midian.' It does not appear that the Midianites exercised their supremacy by any actual form of government. Being chiefly wandering herdsmen, like the Bedouin Arabs of the present day, they were rather in the habit of regularly coming up from the desert 'to destroy the increase of the earth.' So terrible were their marauding expeditions, that it is said they 'left no sustenance for Israel, neither sheep, nor ox, nor ass.' Only in the mountain strongholds, and in dens and caves among the hills, could the people preserve their liberty and the produce of their fields. At last, however, the Israelites began 'to cry unto the Lord,' and a prophet is sent to stir up their religious and patriotic feelings. They were now obviously ripe for resistance to the enemy, at least portions of them. It is at this point that G. is introduced by the writer of the Book of Judges, 'threshing wheat by the winepress to hide it from the Midianites.' The steps which he took to secure the freedom of his countrymen are too well known to require description. It is sufficient to say that, with a small but resolute force of Jewish patriots, he fell suddenly upon the enemy in the neighbourhood of Mount Gilboa, and utterly routed them. The pursuit of the fugitives was continued far across the Jordan towards the Syrian Desert. The effect of the victory was most decisive. The Midianites, we are told, 'lifted up their head no more,' and the land of Israel enjoyed 'quietness forty years in the days of Gideon.' The people wished to make him king, but he religiously refused to tamper with the theocracy. He left behind him 70 sons.

GIEN, a small manufacturing town of France, in the department of Loiret, is situated on the slope of a hill on the right bank of the Loire, 38 miles east-south-east of Orleans. It is well built, is connected with the opposite bank of the river by a handsome stone-bridge of 12 arches, has an old church (the church of St Etienne), which has been much hurt by repairs, and, surmounting the hill, it has an interesting old castle, in a good state of preservation. G. has important manufactures of faïence and leather, and some trade in wine, corn, salt, saffron, and wool. Pop. 5697.

GIESELER, JOHANN KARL LUDWIG, German church historian, was born 3d March 1792, at Petershagen, near Minden, where his father was a clergyman. After attending the orphan-house school and university of Halle, and after teaching for a year in that town, in October 1813, he entered the army as a volunteer during the war of liberation. On the re-establishment of peace, however, in 1815, he returned to his former situation, where he taught for two years, and then became *conrector* of the Gymnasium at Minden. In the following year, he was appointed to the directorship of a newly instituted gymnasium at Cleves, and published an essay on the origin and early fate of the gospels (*Historisch-Kritischer Versuch über d. Entstehung u. d. frühern Schicksale d. schriftlichen Evangelien* (Leipzig, 1818). This and other works were the occasion of his being called, in 1819, as ordinary professor of theology, to the university of Bonn, which had been established but shortly before. It was in this place that he began his great work on church history, of which 3 vols. appeared during his life, and two more after his death, under the editorship of E. R. Redepenning. This work, which brings down the history of the church to the most recent times, has been translated into English, and is so greatly valued for its method of picturing the times in happy quotations from contemporary writings, that the first three volumes have already gone through several editions. In 1831, G. was called to a chair in Göttingen; became, in 1837, a consistorial councillor; and later, also knight of the order of the Guelphs. He was deeply devoted to his professorial duties, but took at the same time a practical interest in many benevolent schemes, especially in the Göttingen orphan-house. Besides numerous contributions to periodicals and publications on contemporary questions, he edited, among other things, the *Narratio de Bogomilis* of Euthymius Zygabenus (Gött. 1842), as well as Petrus Siculus' *Historia Manicheorum seu Paulicianorum* (Gött. 1846), and left behind him a volume on the history of dogmas, which was given to the world by Redepenning in 1856. He died 8th July 1854. A notice of his life will be found prefixed by the editor to the 5th vol. of his *Church History*.

GIESSEN, the principal town of the province of Upper Hesse, in the Grand-duchy of Hesse, or Hesse-Darmstadt, is pleasantly situated in a beautiful and fertile plain at the confluence of the Wieseck and the Lahn, 34 miles north of Frankfurt-on-the-Maine. Pop. about 9000. It is chiefly deserving of notice for its well-endowed university (founded in 1607), which possesses commodious buildings for lecturing, and has well-appointed anatomical and other museums, a good library, observatory, a famous chemical laboratory (where the illustrious Liebig experimented), botanical garden, &c. There are also various endowed schools, as the Gymnasium, Real-Schule, &c., and several institutions for the preliminary instruction of different branches of medical knowledge, which are connected with the university. G. has manufactories for the

preparation of tobacco, liqueurs, vinegar, soap, and leather, and is an active thriving town.

GIFFORD, WILLIAM, an English poet, translator, and critic, was born at Ashburton, in Devonshire, in April 1756. At the age of 15 he was apprenticed to a shoemaker, but exhibiting a very decided bias towards learning and poetry, he was enabled, through the kindness of some friends, to acquire an education, and to proceed to Exeter College, Oxford. G.'s first publication appeared in 1794, being a satirical poem, entitled the *Baviad*, directed against the *Della Crusians* (q. v.). It crushed them in a moment, like the fall of a rock. Flushed with success, G. next year produced the *Mæviad*, which satirised the offences in the high places of the drama. In his third satire, G. assailed *Peter Pindar* (Dr Wolcott); and the coarse and witty doctor, the breath of whose nostrils was literary warfare, rushed to the fray with *A Cut at a Cobbler*, and bespattered his opponent with mud from the kennels. Canning and his friends having at this time set up the *Anti-Jacobin*, G. was appointed editor, and through the influence he acquired among the leaders of at least one section of the political world, he was appointed to offices, the joint emoluments of which amounted to £900 per annum. In 1802, he translated *Juvenal*, and appended to his work a sketch of the poet's life. He edited the works of Massinger, Ford, Shirley, and Ben Jonson, and in his notes assailed former editors with the utmost ferocity. In 1808, he was appointed editor of the *Quarterly Review*, started by Sir Walter Scott and his friends in opposition to the *Edinburgh*. The periodical under his charge attained great influence, and he continued his editorial duties till within two years of his death. He died in London on the 31st December 1826.

G. possessed much satirical acerbity and poison, but as a poet he holds no rank whatever. As annotator and editor of the old English dramatists, he did good service, but his labours in this field are disfigured by suspicion and malignity. As a critic, he was bitterly partial and one-sided, and his praise and blame depended on the political leanings of the writer. Leigh Hunt was to be pursued like a wild-beast, because he was a Liberal; and the flower-garden of *Endymion*, every rose of which was fed by the dews of paradise, was to be trampled upon with critical hoof, because Keats was known to have written a sonnet in praise of Hunt, and was understood to be his private friend. G. had been rudely nurtured; he lived in a time of great political uncharity; and if a portion of the bitterness he displayed may be set down to natural disposition and turn of mind, the larger part, perhaps, must be explained by the pressure of the times in which he lived.

GIFT, in English Law, means a gratuitous transfer of property. Any person is at liberty to do what he pleases with his own property, and to give it away with or without consideration, if he is so inclined. When he gives away goods or chattels, mere delivery of possession, accompanied by words of gift, is sufficient to transfer the property; and then the transaction is irrevocable. But if he does not give possession of the goods at the same time, then, in order to be binding upon him, he must execute a deed or writing under seal. The reason of this is, that a mere verbal promise, without some legal consideration, is nugatory and revocable; whereas, when he executes a deed, he is stopped from ever afterwards denying it. Where the property given is not personal, but real, then a deed is in general absolutely necessary to transfer the property. A will is the most familiar example of

a gift of property both real and personal, for the testator generally, in such a case, gives away his property gratuitously. Each gift of personalty by will is better known under the name of a legacy; and a gift of land is generally called a devise.

As sometimes the power of giving away property gratuitously is abused, in order to defraud and defeat creditors, it is provided by statute, that a voluntary conveyance, whether of chattels or land, made by a person who is at the time insolvent, shall be void as against such creditors; and they are entitled, accordingly, to recover the property from the donee (13 Eliz. c. 5). The gift, however, even in such a case, stands good against the donor himself. So, if any person give by deed gratuitously any land, and then sell the same land, the gift will be void against the *bona-fide* purchaser (27 Eliz. c. 4).

There is a peculiar kind of gift, or rather a gift made in peculiar circumstances, called a *Donatio Mortis Causa*, i. e., a gift made by a person on death-bed of some personal property, such as chattels, money, bills of exchange, &c. Such gifts are held good, if they comply with certain conditions. This is in substance a mode of giving personal chattels to a particular individual, without the necessity or intervention of a will; but such gifts are so often afterwards disputed, that it is better to include them in a will.

In Scotland, a gift may be made of goods in the same manner as in England; but it is usually called a *Donation* (q. v.). Gratuitous alienations by persons in insolvent circumstances are also held to be void as against creditors (stat. 1621, c. 18). Though it is competent in Scotland to make a gift of goods or money by merely delivering the possession thereof, accompanied by words of gift to the donee, still there is this peculiarity, that if the transaction is afterwards impeached, it can only be proved in Scotland by the donor's writ or oath, no matter how many witnesses may have been present; whereas, in England, it can be proved by ordinary witnesses, like any other fact.

Gift, in the Law of Scotland, is also often used to denote a grant or appointment by the crown or a court, such as gifts of non-entry, escheat, bastardy, tutory, &c.

GIGG, GIGA, or GIGUE, the name of a short piece of music, much in vogue in olden times; of a joyful and lively character, and in $\frac{3}{4}$ or $\frac{1}{2}$ time, sometimes in $\frac{3}{8}$; used formerly as a dance-tune, and often introduced as a movement of a larger composition. It consists of two parts of eight bars each, and the shortest notes are quavers.

GIJÓN, a fortified town and seaport of Spain, in the province of Oviedo (the former Asturias), and 20 miles north-north-east of the town of that name, stands on a low peninsula projecting northward into the Bay of Biscay. It is the best and most regularly built town in the province; is partly surrounded by old walls, and is defended by an old castle and by coast batteries. It has a good port, at which steamers call regularly. There are manufactures of stone-ware, hats, and linen fabrics; nuts and other fruits are exported. Bermudez, the historian of Spanish art, was born here. In 718, the Moors having been defeated at the battle of Canicas, were compelled to abandon G., of which they had made themselves masters. Pop. 6100.

GIL, SAN (sometimes called *St Giles*), a small town of the republic of New Granada, in the department of Boyaca, stands in lat. 6° 25' N., and in long. 73° 40' W., 64 miles south-west of Pamplona. It was founded in 1690, has a college and manufactures of tobacco and cotton fabrics, and a good trade in agricultural produce. Pop. 6000.

GIL, VICENTE, the father of the Portuguese drama, was born about 1470, or, according to others, about 1485, whether at Guimaraes, Barcellos, or Lisbon, is disputed. In accordance with the desire of his parents, he studied jurisprudence at the university of Lisbon; but his poetical tastes soon drew him away from that science, and his inclination was possibly confirmed by the favourable reception of his first poetical essay at the court of Emanuel the Great. This was a pastoral in Spanish, which was represented before the court in 1502, to celebrate the birth of the prince who became John III. The queen, Beatrice, Emanuel's mother, was so pleased with the piece, that she wished it to be repeated at the following Christmas; but G. produced a new work for the occasion, also in Spanish, and in dramatic form; so that the introduction of the drama into Portugal coincides with the year of the birth of John III. G. continued at all the more important festivals to produce similar dramatic pieces, in the performance of which not only he and his daughter Paula, who was a distinguished actress and poet, but King John also took part. His fame spread beyond his own country, and Erasmus, declaring him to be the greatest dramatist of his time, is said to have learned Portuguese for the purpose of reading his works. At home, however, he had detractors, whom he sought to silence once at a party by composing impromptu, on a given proverb, the farce, *Inez Pereira*, which is his best piece. Complaints in his works seem to indicate that the court was not liberal enough to keep him from want in his later years. He died probably soon after 1536. His works were edited by his son in 1561, and again in 1585, after undergoing castigation by the Inquisition. It was not till our own times that a reprint of G.'s works, as complete and correct as possible, was undertaken by Barreto Feio, and Monteiro (3 vols., Hamb. 1832). Not only does G. possess historical importance as having laid the foundation of a national theatre in Portugal, but his works deserve study from their intrinsic poetical and dramatic worth. He has been called the Plautus of Portugal.

GIL POLO, GASPAS, a Spanish poet, was born at Valencia in the first half of the 16th century. While town-clerk of his native place, his talents for office became known to Philip II., who appointed him, in 1572, coadjutor to the president of the upper financial chamber of the kingdom of Valencia, and in 1580 sent him to superintend the royal patrimony at Barcelona, where he died. Before, however, his time was absorbed by business, G. had occupied himself with poetry. Besides various lyrics, and his *Canto de Turia* in praise of his native city, he wrote a continuation of Montemayor's *Diana*, under the title *Primera Parte de Diana enamorada Cinco Libros, que prosigue los Sieta de Jorge Montemayor*. This work appeared first at Valencia in 1564, the same year in which another continuation of Montemayor's pastoral was given to the world by a physician named Perez. Though inferior to the original romance in invention, G.'s continuation so greatly surpasses it, as well as the other continuation, in clearness of thought and expression throughout the metrical portions, that Cervantes exempts it from the condemnation of Don Quixote's other books as deserving as much respect 'as though Apollo himself had written it.' The best edition of the *Diana enamorada* is that of Cerda, which is accompanied by a commentary on the *Canto de Turia* (Madrid, 1778; new ed. 1802). Biographers have generally confounded G. with a son of his own name, who was a distinguished writer on jurisprudence.

GILA, RIO, a river of North America, has its origin in the state of New Mexico, in lat. about 32° 45' N., long. about 108° 30' W.; and, after a westward course of nearly 450 miles, joins the Colorado, about 70 miles above the fall of that river into the Gulf of California. For more than one-half of its course it passes through mountains, and in some places is wholly inaccessible, being imprisoned within walls of perpendicular rock nearly 1000 feet high. The G. is navigable for flat boats for about 180 miles. Numberless ruins of stone-built houses, among which fragments of pottery are found, occur all along the banks of this river, proving that at some past period the district must have been much more populous than it now is. One of these ruins, a structure of three stories in height, is still in a good state of preservation.

GILBERT, WILLIAM, a distinguished natural philosopher and physician, was born in 1540 at Colchester, of which town his father was recorder. He was a member, and subsequently fellow of St John's College, Cambridge; was B.A. in 1560, M.A. in 1564, and M.D. in 1569. About the year 1573, he settled in London, joined the College of Physicians, and practised with so much reputation, that he was appointed physician to Queen Elizabeth. The time that he could spare from the duties of his profession was employed in philosophical experiments, particularly in relation to the magnet; and in these he was assisted by a pension from the queen. After holding various offices in the College of Physicians, he was finally elected its president in 1600. At the death of the queen, he was continued in his office of court physician by James I., but he survived his royal mistress only a few months, and died a bachelor in November 1603. His death seems to have taken place in London; but he was buried at Colchester, in the church of the Holy Trinity, where there is a handsome monument to his memory. He left his library, globes, instruments, and cabinet of minerals to the College of Physicians. From his birthplace, he is generally designated as Gilbert of Colchester. His works are (1) *De Magnete, Magneticisque Corporibus, et de Magno Magnete, Tellure, Physiologia Nova*, fol., Lond. 1600 (reprinted at Stettin in 1633), of which there are several editions; (2) *De Mundo nostro Sublunari Philosophia Nova*, 4to, Amsterdam, 1651 (published from a MS. in the library of Sir William Boswell). The first of these works has served as the basis of most subsequent investigations on terrestrial magnetism; and (to use the words of Professor Whewell in his *History of the Inductive Sciences*) it 'contains all the fundamental facts of the science, so fully examined, indeed, that even at this day we have little to add to them.' He establishes the magnetic nature of the earth, which he regards (as the title of his work indicates) as one great magnet; and he conjectured that terrestrial magnetism and electricity were two allied emanations of a single force; a view which was only demonstrated with scientific strictness more than two centuries afterwards by Oersted and Faraday. G. was the first to use the terms 'electric force' and 'electric attraction,' and to point out that amber is not the only substance which when rubbed attracts light objects, but that the same faculty belongs to the resins, sealing-wax, sulphur, glass, &c.; and he describes how to measure the excited electricity by means of an iron needle moving freely on a point. Galileo pronounced him 'great to a degree that might be envied,' and the publication of his treatise *De Magnete* will always be regarded as constituting an epoch in the history of magnetism and the allied sciences.

GILBERT ISLANDS, a group on the south-west coast of the archipelago of Tierra del Fuego, offer a good harbour in Doris Cove.—Another cluster of the same name, comprising 15 coral islands, forms part of the Mulgrave Archipelago in the Pacific, between lat. 1° S. and 2° 30' N., and long. 172° and 174° 30' E., and contains a population of 60,000. The two largest are known as Drummond's Isle and Knox's Isle; the former 30 miles long by rather more than $\frac{1}{2}$ mile broad, the latter 20 miles long. The inhabitants resemble the Malays in appearance, and are divided into three classes—chiefs, landholders, and slaves. The chief, almost the only, cultivated products are the cocoa-nut and the pandanus.

GILBERTINES, a religious order in the Roman Catholic Church, specially noteworthy as being of English origin. It was founded in the twelfth c. by St Gilbert, a native of Sempringham, in Lincolnshire. The rule of the order was mainly derived from that of the Canons Regular of St Augustine. St Gilbert also founded an order of nuns after the Benedictine institute. Both orders were approved, and had numerous convents in England at the time of the Reformation, when they shared in the general suppression.

GILBOA, a Hebrew word signifying 'bubbling fountain,' is the name given in the Old Testament to a range of hills, between 500 and 600 feet high, overhanging the city of Jezreel, in the eastern side of the plain of Esdraelon. It is memorable as the scene of the defeat and death of King Saul and his three sons.

GILD. See **GUILD**.

GILDAS, or **GILDUS**, by some surnamed the Wise, by others Badonicus, appears to have been born in the year 516. He visited France in 550, and Ireland in 565. He died in 570. His *De Excidio Britanniae Liber Querulus* was first printed at London in 1525, and has been often reprinted both in England and on the continent. The best editions are Mr Stevenson's, published by the English Historical Society (Lond. 1838), and Mr Petrie's in the *Monumenta Historica Britannica* (Lond. 1848). G. is a weak and wordy writer. Gibbon has justly described him in a single sentence: 'A monk, who, in the profound ignorance of human life, has presumed to exercise the office of historian, strangely disfigures the state of Britain at the time of its separation from the Roman empire.' His obscure and meagre narrative may be divided into two periods—the first extending from the first invasion of Britain by the Romans to the revolt of Maximus, at the close of the 4th c.; the second, from the revolt of Maximus to the author's own time. The second portion is even more unsatisfactory than the first.

GILDING. There are many processes of gilding, varying with the nature of the substance to be gilded, and the kind of effect required to be produced, but they may all be classified under three heads—namely, 1st, mechanical gilding; 2d, chemical gilding; 3d, encaustic gilding.

The first is used chiefly for gilding wood, plaster of Paris, and other compositions, in imitation of wood-carving. It consists simply in laying leaf-gold upon the surface of the article, which is first prepared with a layer of *thin white*, composed of hot size and whiting; then, if the gilding is to be burnished, another layer of *thick white* of similar composition, but with more whiting, is added; after this, a coating of gold-size (see **GOLD-SIZE**) is brushed over; this is wetted, and the gold-leaf is laid upon it. A considerable amount of skill is required in picking up, cutting into the proper size, and laying on the pieces of gold-leaf, so that

there shall be as little waste as possible, and all the inequalities of a raised design equally covered. The gold-leaves are first spread upon a cushion by blowing them from between the leaves of a book, then cut into the required sizes, and lifted and laid on the work by means of a *tip*, which is a sort of comb formed of bristles. When the gold is thus laid on, it is forcibly blown to expel as much as possible of the moisture under it, and then further pressed and smoothed by means of a camel-hair brush. When it has reached a certain state of dryness, it is burnished by rubbing with a burnisher of flint or agate. The use of the under-layer of whiting and size is to give a somewhat yielding surface, which renders it possible to rub the gold-leaf briskly with the burnisher without abrading it. Portions of the surface which are left unburnished in dead-gold are called the *mat*. The above process is called *burnish gilding*. Oil gilding differs somewhat from this in the preparation of the surface to receive the gold-leaf. Two or three coatings of thin white, mixed with a little mallow clay, are applied; then two or three coats of plain gelatine-size, called *clear coat*; and finally, the oil gold-size (see **GOLD-SIZE**), upon which the gold is laid when it is nearly dry or *tacky*. Those parts which require burnishing are treated as before described. *Japan gilding* will be described under **JAPANING**.

Chemical gilding.—Metals are now usually gilded by the process of electro-gilding (see **GALVANISM**), but besides this, various methods of chemical gilding have been adopted, and some are still in use.

Water gilding, as it is very inappropriately termed, is conducted by applying to the surface to be gilded a thin coat of an amalgam of gold, and then by heat driving off the volatile mercury, when the gold remains adhering firmly to the surface, but having a dull and dingy brownish-yellow colour. The colour and lustre of gold is brought up by *scratching* with a wire-brush, or burnishing with a bloodstone, or black hematite burnisher. The amalgam of gold is made by dissolving leaf-gold or precipitated gold in about ten times its weight of mercury, and then washing and straining it through wash-leather. The surface to be gilt is usually prepared by dipping it in a solution of nitrate of mercury, or *quick-water*, after it has been well cleaned; this coats it with a film of mercury, and insures adhesion of the amalgam. Water gilding is very injurious to the men and women who work at it, on account of the mercurial fumes. Modern improvements in the construction of the furnace, where the 'drying off' is conducted, have diminished this evil considerably, and at the same time economised the process by recondensing and saving the evaporated mercury; but still, with the best arrangements, the health of the water gilders is affected. This process is only applicable to metals that readily form an amalgam with mercury. Iron and steel, therefore, cannot be directly gilded by it. It is still in use for buttons and some kinds of common jewellery. Thirty thousand buttons, one inch in diameter, may be gilded with one ounce of gold; 14 or 15 thousand is the number over which this quantity is commonly spread.

Gilding by immersion.—For this purpose a solution is used which slowly attacks the metal to be gilded, and at the same time deposits on its surface an equivalent of gold. Elkington's patent solution is made by dissolving $\frac{1}{2}$ ounce troy of fine gold in 2 $\frac{1}{2}$ ounces of nitro-muriatic acid, heating this until red and yellow vapours cease to be evolved, then diluting with 1 $\frac{1}{2}$ pint of distilled water, adding to this 1 pound of bicarbonate of potash, and boiling for two hours. The article to be gilded is dipped

GILDING METAL—GILLIES.

into this at nearly the boiling heat, and agitated in it for about a minute. Talbot's patent solution is made by adding a solution of gold to a solution of gallic acid in water, alcohol, or ether. The articles are dipped as above.

The method called *Grecian gilding* is a process intermediate between the above and water gilding. Sal ammoniac and corrosive sublimate are dissolved in nitric acid, and gold is dissolved in this solution, which thus becomes a mixture of chloride of gold and nitrate of mercury with some ammonia. This solution, on being applied to a surface of silver, immediately blackens it, but upon the application of heat, it is richly gilded.

Most articles that are gilded by either of the above chemical methods, or by electro-gilding, are submitted to an after-process of *colouring*. This consists either in acting upon the surface with a saline solution, and heating the article afterwards, or in coating it with a kind of varnish of bee's-wax and yellow-ochre, and then burning it off. Various saline solutions are used, many of which are carefully guarded trade secrets. 1 oz. alum, 1 oz. of common salt, and 2 oz. nitre dissolved in half a pint of water is recommended. Also 24 parts of nitre, 10 alum, 5 sulphate of iron, 5 sulphate of zinc boiled together in sufficient water to form a paste when cooled with continual agitation. The articles are immersed in this, and then heated till the desired colour is obtained.

Cold Gilding.—For this a gilding powder is first prepared by dissolving 5 drams of pure gold and 1 dram of copper in 10 oz. of nitro-muriatic acid, then moistening clean linen rags with the solution, and burning them to ashes. These ashes contain finely divided gold, which may be applied to surfaces of copper, brass, or silver, by simply rubbing it over them with a piece of cork moistened with a solution of common salt in water.

Sword-blades, lancets, and other steel articles are gilded in fancy devices by drawing the design with a camel's-hair pencil moistened in a solution of gold, prepared by agitating ether with a solution of terchloride of gold, and decanting the light liquid which floats on the top. Naphtha may be used in the same manner for this purpose, and is much cheaper.

Silks, satins, ivory, bone, &c., may easily be gilded by immersing them in a neutral solution of 1 part of terchloride of gold to 4 or 5 of water, and then exposing them to the action of hydrogen gas, which readily combines with the chlorine, and reduces the gold to the metallic state. Flowers, and other ornamental designs, may be thus produced in gold by simply painting them on the surface with a camel's-hair brush dipped in the gold solution. The articles may then be suspended in an inverted tumbler or other suitable vessel, which, if placed over a bottle containing dilute sulphuric acid and iron filings or zinc scraps, will collect sufficient of the light gas to bring out in a few minutes a beautiful and permanent pure gold surface.

Encaustic gilding is usually applied to glass and porcelain. The gold is first obtained in a finely divided state by precipitating from the chloride with protosulphate of iron, or by simply heating the chloride. This powder is ground up with $\frac{1}{4}$ of its weight of oxide of bismuth and some borax and gum water, and then painted on the ware. It is then heated till the borax is vitrified and the gold thereby fixed. Sometimes the gold is ground with turpentine, or an amalgam of gold is used. It has a brown dingy appearance when it leaves the kiln; the gold lustre is brought up by burnishing.

GILDING METAL. The metal of which gilded goods are made, is required to have as 'early as

possible the colour of gold, so that when the surface-gilding is worn off at the more exposed parts, the difference of colour will not be readily apparent. This is obtained by making a kind of brass having a much larger proportion of copper than in common brass.

The following are three receipts from among : variety in use : 1st, 6 parts copper, 1 common brass ; 2d, 4 parts copper to 1 Bristol brass ; 3d, 13 parts copper, 3 parts brass, 12 parts tin. The last is much harder than No. 1 or 2.

GILEAD (in Eng. 'region of rocks') was a mountainous district on the east side of the Jordan, bounded on the N. by the river Hieromax (the modern *Sheriat-al-Mandhar*), which separated it from the rich levels of Bashan ; on the E. by the desert table-lands of Arabia ; on the S. by Moab and Ammon ; and on the W. by the Jordan. In spite of its name, the vegetation is luxuriant, especially in the middle, and round the brook Jabbok, where forests of oak and terebinth occur. The hills are not very high ; they have broad summits almost like table-lands, 'tossed,' says Professor Stanley (*Sinai and Palestine*), 'into wild confusion of undulating downs.' G. anciently produced gums and spices. It was given by Joshua to the tribes of Gad and Reuben, because of the multitude of their cattle, and as a frontier land was much exposed to invasion.

GILFILLAN, GEORGE, critic and essayist, was born at Comrie in 1813. He studied at the university of Glasgow, and at the divinity hall of the Secession body, afterwards the United Presbyterian Church, and in 1835 he was licensed to preach the gospel. In March 1836 he was ordained to the School Wynd Church, Dundee. His works are numerous. They display a rich but reckless fancy, and wide literary sympathies, although deficient perhaps in refinement of taste. The principal are, *A Gallery of Literary Portraits* (1846) ; a second *Gallery* (1849) ; *The Bards of the Bible* (1850) ; *The Martyrs, Heroes, and Bards of the Scottish Covenant* (1852) ; a third *Gallery of Literary Portraits* (1854) ; *History of a Man* (1856) ; *Christianity and Our Era* (1857) ; and *Alpha and Omega* (1860). In 1853 he commenced an edition of the *British Poets*, published by Nichol of Edinburgh, which extended to 48 vols. His contributions to periodicals have been numerous.

GILL (Low-Lat., *gilla*, a drinking-glass), a measure of capacity, containing the fourth part of a pint, or the 32d part of a Gallon (q. v.).

GILLE'NIA, a genus of plants of the natural order *Rosaceæ*, sub-order *Spirææ* ; perennials, natives of the temperate parts of North America. The roots are used in medicine as a mild emetic, and in small doses as a tonic, and are often called *INDIAN PHYSIC*, sometimes *American Ipecacuanha*, *Indian Hippo*, *Droopwort*, and *Bowman's Root*. They are sometimes planted in shrubberies, on account of their graceful foliage. They grow to the height of about two feet.

GILLES, St., an old town of France, in the department of Gard, is situated near the borders of the department of Bouches du Rhone, on the Canal de Beaucaire, 12 miles south-south-east of Nîmes. Its abbey church, the west front of which is a master-piece of Romanesque architecture, and is covered with the richest decoration, dates from the 11th c., and is the most notable building in the town. The neighbourhood of St G. produces a strong red wine which is exported. Pop. 5730.

GILLIES, JOHN, LL.D., known as a classical historian, the son of Robert Gillies, Esq., was born

at Brechin, Forfarshire, January 18, 1747. His youngest brother, Adam, was a judge of the court of session in Scotland, under the title of Lord Gillies. G. was educated at the university of Glasgow; and, after a time, took up his residence in London, with the view of following literature as a profession. He subsequently acted for several years as travelling tutor to the sons of John, second Earl of Hopetoun, who in 1777 settled upon him an annuity for life. In 1778 he published a translation of the *Orations of Isocrates and those of Lysias, with some Account of their Lives*, 4to; and in 1786 appeared the first part of his *History of Ancient Greece*. This work forms 2 vols. 4to, and 4 vols. 8vo. It was extremely popular on its first appearance, and is really far from being a discreditable performance, though much disfigured by verbosity, and dull and prolix disquisition; but it has dropped out of notice nearly altogether since the advance of Greek scholarship in the present century, and the publication of the histories of Thirlwall and Grote. His *View of the Reign of Frederick II. of Prussia* appeared in 1789, 8vo. In 1793, on the death of Dr Robertson, he was appointed historiographer to the king for Scotland, with a yearly salary of £200. His other works are, a translation from the Greek of *Aristotle's Ethics and Politics: comprising his Practical Philosophy, with Notes, the Critical History of his Life, and a new Analysis of his Speculative Works*, 2 vols.; *Supplement to the Analysis of Aristotle's Speculative Works* (1804); *History of the World from Alexander to Augustus*, 2 vols., 4to (1807-1810); *Translation of Aristotle's Rhetoric* (1823). He died February 5, 1836.

GILLS. See RESPIRATION, ORGANS AND PROCESS OF.

GILLYFLOWER, a popular English name for some of the cruciferous plants most prized for the beauty and fragrance of their flowers, as wall-flower, stock, &c. The clove-pink also, the wild original of the carnation, is called *Clove-Gillyflower*. The name G. has been regarded as a corruption of *July-flower*; but in Chaucer it appears in the form *gilafre*; and the French *girafée* indicates the true derivation from *girafe*, a clove, the smell of the Clove-G. being somewhat like that of cloves.

GILO'LO, or **ALMAHERA**, one of the Moluccas or Spice Islands, and the chief of a group of the same name, is crossed by the equator in long. 128° E. In its general outline it bears a vague resemblance to its western neighbour Celebes, from which it is separated by the Molucca Passage, both of them being as unlike in form to any other island as they are like to each other. It is divided towards the east from New Guinea by a wide channel of its own name. It contains about 6500 square miles, comprising several petty states, which are connected chiefly with the Dutch settlements in the East Indies. The imports are manufactured goods, opium, china-ware, and iron; and the exports are sago, cocoa-nuts, spices, fruits, pearls, gold-dust, horses, sheep, and horned cattle. The interior is mountainous, and in many parts densely wooded.

GILRAY, JAMES, a celebrated caricaturist, born in London about the middle of last century. He first became known as a successful engraver about 1784, and between 1779 and 1811 issued as many as 1200 caricatures, numbers of which, it is said, 'were etched at once upon the copper without the assistance of drawings.' They are full of broad humour and keen satire, the subjects of his ridicule being generally the French, Napoleon, and the ministers, though he often diverged to assail the social follies of his day. He died 1st June 1815. G.'s drawings have often been published, but the best edition is

that of M'Lean (accompanied by an illustrative description), in 304 sheets (Lond. 1830). More recently, an edition has been issued by Bohn.

GILTHEAD (*Chrysophrys*), a genus of scapthopterous fishes of the family Sparidae, having a deep compressed body, a single dorsal fin, the anterior rays of which are spinous, the cheeks and gill-covers covered with scales, the teeth of two kinds, six conical teeth in front of each jaw, and four rows of oval rounded grinding-teeth in the upper jaw, three rows in the lower. They feed chiefly on mollusca, the shells of which their teeth enable them to crush to pieces. The species are numerous; inhabitants of the warmer seas. One

Common Gilthead (*Chrysophrys aurata*).

species, the **COMMON G.** (*C. aurata*), is found, but rarely, on the British coasts; it abounds in the Mediterranean, and is very much esteemed for the table. It seldom attains a length of more than twelve inches. It is generally found near the shore, in small shoals, and its presence is sometimes betrayed to fishermen by the noise which its teeth make in crushing shells. It is said to agitate the sand with its tail, in order to get at the mollusca concealed in it. The back is silvery gray, shaded with blue; the belly like polished steel, the sides have golden bands; and there is a half-moon-shaped golden spot between the eyes, from which it derives the name G., the Latin name *Aurata* (gilded), and the Greek name *Chrysophrys* (golden eyebrow). From the Latin *Aurata* comes the French name *Dorada*. This fish was very generally kept in the vivaria of the ancient Romans, being much valued and easily fattened. Another species (*C. microdon*) is also found in the Mediterranean.—The name G. is also given to a British fish of a different family (*Labridæ*), a species of Wrasse (q. v.).

GILT TOYS. This term is known in trade as a designation for small articles which are gilded, but is chiefly applied to the cheap jewellery which is almost exclusively manufactured at Birmingham. In that town this trade is very extensive, and employs thousands of persons and a considerable amount of machine power. Cheap jewellery of the most elegant forms is made from copper, which is drawn through rollers for the purpose, into small ribbons and wires, with elegantly embossed surfaces to represent the fine chasing employed on articles made from the precious metals. These the gilt-toy maker twists and solders into brooches, bracelets, rings, and a variety of trinkets, usually with a raised bezel for receiving a piece of polished coloured glass, or a cheap stone. Previous to setting the glass or stone, the trinkets are strung on copper wires, and sent to the electro-plater, who gives them a coating of gold or silver, and returns them to the gilt-toy maker, who finishes them by burnishing and by setting the imitation gems. In this way really beautiful imitation jewellery is produced at an incredibly small cost; and being coated with the precious metals in the pure state in which they are deposited by the electro-plating process, their

spurious character is not easily detected by the uninitiated.

GIMBALS (Lat. *gemellus*, a twin), are two circular brass hoops used for suspending the compass-box on board ship, so that it may always rest horizontally, unaffected by the ship's motion. The outer hoop is attached to a box or other fixed object, while the inner is constructed so as to allow of its moving freely within the outer, to which it is attached by two pivots at the extremities of a diameter. The compass-box is attached to the inner hoop by two similar pivots at right angles to the former. Thus, the compass moves freely in two directions at right angles to each other, and can always retain its horizontal position, however the vessel may roll or pitch. G. are often applied to other instruments, such as the mountain barometer, &c.

GIMBLET, a tool for boring holes in wood to receive nails, screws, &c., and generally used when the hole is to be larger than can be bored with a brad-awl. It has a conical screw point, followed by a groove for clearing, and is fitted in a cross or T handle. An improvement has lately been made by twisting the grooved part of the gimblet, so that it forms a long spiral groove.

GIMENA, or XIMENA. See **JIMENA**.

GIMP, or GYMP, a kind of trimming for dress, curtains, furniture, &c., made either of silk, wool, or cotton. Its peculiarity is that fine wire is twisted into the thin cord of which it is made.

GIN is a machine used for raising weights, driving piles, &c., and consists of three poles, each from 12 to 15 feet long, and 5 inches in diameter at the lower end, tapering to 3½ inches at the upper. The poles are united at the top, either by an iron ring which passes through them, or by a rope which is twisted several times round each, and to this 'joint' a pulley is fixed. Two of the poles are kept at an invariable distance by means of an iron rod, in order that they may support the windlass which is attached to them, its pivots running in iron cheeks fixed to the poles. When the machine is to be used, it is set up over the weight to be raised; two blocks arranged according to the Second System of Pulleys (q. v.) are fixed, one to the top of the poles, the other to the weight; and the rope, after passing round both blocks, and over the pulley before-mentioned, is attached to the windlass, by the revolution of which the weight can then be raised.—The name of Gin is also given to a machine used for raising coal, &c., and also for communicating motion to thrashing-mills. It consists of an erect axis or drum, firmly fixed in sockets, to which are attached transverse beams, varying in number according to the power required. To the extremity of each beam a horse is yoked, and they are then driven round in a circle. If coal is to be raised, the horses must either be frequently unyoked, and turned in the opposite way, or the machine must be made reversible; the latter of which is found to be preferable, as a saving both of time and labour. This machine is now rapidly disappearing before the steam-engine.

GIN is a machine used for disentangling the fibres of Cotton (q. v.).

GIN, or GENEVA, an alcoholic drink, distilled from malt or from unmalted barley or other grain, and afterwards rectified and flavoured. The gin, which forms the common spirituous drink of the lower classes of London and its vicinity, is flavoured very slightly with oil of turpentine and common salt; each rectifier has his own particular recipe

for regulating the quantities to be used; but it is usually about 5 fluid ounces of spirit of turpentine and 3½ lbs. of salt mixed in 10 gallons of water; these are placed in the rectifying still, with 80 gallons of proof corn-spirit, and distilled until the feints begin to come over. It is then used either unsweetened or sweetened with sugar.

We derive the terms gin and geneva from the Dutch, who call the Hollands-gin (which is their national spirit) *giniva*, which they have derived from the French *genièvre*, juniper. The origin of this name is, doubtless, to be found in the employment of juniper-berries in flavouring the spirit made from unmalted Riga rye in Holland, where it is an article of great manufacture, chiefly at Schiedam; hence it is often called *Schiedam* or *Hollands*, as well as geneva and gin. So extensive is the manufacture of this spirit in Holland, that in Schiedam alone there are 175 distilleries, employing nearly 1000 men, besides which there are 30 more distilleries in Gouda, and 17 in Amsterdam, and others scattered about the country. Notwithstanding this immense manufacture of alcohol, the Dutch are by no means an intemperate people: the fact is, the larger part by far of the spirit made in Holland is exported to other countries, especially to North America and Northern Europe. It was formerly always exported in bottles, but casks are now much used as well. The chief manufactories of gin in England are those of Messrs Booth and Messrs Smith and Nicholson, in London; Messrs Coates and Co., at Plymouth; and one or two large distilleries in Bristol.

Perhaps nothing used as diet by man is liable to greater and more injurious adulteration than gin. Almost every gin-shop keeper in London has some vile recipe for increasing the pungency and giving a factitious strength to the much diluted sweetened spirit sold under this name. A mere enumeration of the articles usually employed will give some idea of the extent to which sophistication is carried on with this spirit: roach alum, salt of tartar (carbonate of potash), oils of juniper, cassia nutmeg, lemons, sweet fennel, and caraway; coriander seeds, cardamoms, and capsicums; and worse than all, creasote, which is most injurious. It is said that sulphuric acid is even added, but this is by no means probable.

GI'NGAL, a weapon used by Asiatic armies in the defence of fortresses. It may be described as a large and rude musket, which is fired from a rest. The Chinese employ it to a considerable extent.

GI'NGEE is one of the Virgin Islands—the group at the north-east bend of the grand arch of the West Indies.

GINGER (*Zingiber*), a genus of plants of the natural order *Scitamineæ* or *Zingiberaceæ*, having the inner limb of the perianth destitute of lateral inner lobes, and the fertile stamen prolonged beyond the anther into an awl-shaped horn. The species are perennial herbaceous plants, with annual stems, and creeping root-stocks (*rhizomes*); the stems produce leaves in two opposite rows; the flowers are in compact spikes with bracts. They are natives of the East Indies. The root-stocks of most of the species are used as a condiment and in medicine. The most valuable and generally used are those of the Common G. (*Z. officinale*), sometimes distinguished as the Narrow-leaved G., which has been cultivated in the East Indies from time immemorial, and is now also cultivated in other tropical countries, particularly the West Indies and Sierra Leone, from both of which, as well as from the East Indies, its root-stocks—the ginger of commerce—are a considerable article of export. The root-stock is about the

thickness of a man's finger, knotty, fibrous, and fleshy when fresh. The stems which it sends up are reed-like, invested with the smooth sheaths of the leaves, generally three or four feet high. The leaves are linear-lanceolate and smooth. The flowers are not produced on the leafy stems, but on short leafless stems (scapes), in spikes about the size of a man's thumb, and are of a whitish colour, the lip streaked with purple. The cultivation of *G.* is extremely easy

Common Ginger (*Zingiber officinale*):
a, a flower, detached; b, perfect anther.

wherever the climate is suitable. In India it is carried on to an elevation of four or five thousand feet on the Himalayas, in moist situations. The root-stock is taken up when the stems have withered, and is prepared for the market either by seething and scalding in boiling water—in order to kill it—and subsequent drying, or by scraping and washing. The first method yields *Black G.*, the second *White G.*; the blackest of *Black G.*, however, being only of a stone colour, and the whitest of *White G.* very far from perfectly white, unless bleaching by chloride of lime be afterwards employed, as it not unfrequently is, to improve its appearance, a process not otherwise advantageous. There is a considerable difference, however, in the original colour of the root-stock in the *G.* of different countries, which is supposed to be owing to difference in the varieties cultivated. The uses of *G.* both in medicine, as a stimulant and carminative, and in domestic economy, as a condiment, are too well known to require particular notice. Its qualities depend very much on a pale yellow volatile oil, lighter than water, called *Oil of Ginger*. It contains also a considerable quantity of starch.—*Candied G.*, or *Preserved G.*, consists of the young root-stocks preserved in sugar, and is now imported in considerable quantity from China, as well as from the East Indies and from the West Indies. It is a delicious sweetmeat, and is useful also as a stomachic.—*Essence of G.*, much used for flavouring, is in reality a tincture, prepared of *G.* and alcohol.—*Syrup of G.* is used chiefly by druggists for flavouring.—*Ginger Tea* is a domestic remedy very useful in cases of flatulence, and is an infusion of *G.* in boiling water.—*Ginger-beer* (q. v.) is a well-known beverage, flavoured with ginger.—*Ginger Wine* (q. v.) is a cheap liqueur flavoured with ginger.—*G.* was known to the Romans, and is said by Pliny to have been brought from Arabia.—Another species of *G.* is *ZERUMBER* (*Z. zerumbet*), also called Broad-leaved

G., cultivated in Java, and of which the root-stock is sometimes erroneously called Round Zedoary. The root-stock is much thicker than that of common *G.*, and is less pungent.—The root-stock of the *CASUMUNAR* (*Z. casumunar*), sometimes called Yellow Zedoary, has a camphor-like smell, and a bitter aromatic taste. It acquired a high reputation as a medicine in England and throughout Europe about the close of the 17th c., but having been extolled not merely as a stimulant and stomachic, but as possessing virtues which did not in reality belong to it, it soon sunk into oblivion.—The root-stock of the *MIOGA* (*Z. mioga*) is less pungent than *G.*, and is much used in Japan.—Cattle sent to graze in the jungles of Northern India, during the rainy season, are supplied with the root-stocks of a species of *G.* (*Z. capitatum*), to preserve their health.—The root of *Aristolochia* (q. v.) *Canadensis* is sometimes called *Indian G.* or *Wild G.* in North America, and is used as a substitute for ginger. It has a grateful aromatic odour and taste, and is stimulant, tonic, and diaphoretic.

GINGER-BEER. An effervescing drink made by fermenting ginger, sugar, and some other ingredients, and bottling before the fermentation is completed. The following recipes are amongst the best known: Lump sugar, 5 lbs.; crushed Jamaica ginger (the unbleached is best), 5 oz.; cream of tartar, 4 oz.; 10 lemons, sliced; and 5 gallons of boiling water. They should be mixed in a vessel which can be kept covered until cool, but require stirring from time to time as the cooling goes on. When lukewarm, add 10 oz. of yeast, and keep it in a warm place to encourage the fermentation, which soon commences; after one day's fermentation, strain through a flannel filter, and let it stand to ferment again for a short time; then take off the scum, and bottle. The bottle must be tied or wired down. Another recipe is: Cream of tartar, 3 oz.; ginger, 1 oz.; refined sugar, 1½ lbs.; 1 sliced lemon; 1½ gallons boiling water; 1 oz. yeast; to be treated in the same way. A spurious ginger-beer, largely used, is made by putting a few drops of tincture of ginger and a little syrup in a bottle, and filling it up with aerated water from the soda-water machine.

GINGERBREAD. A very well-known article of food, which has been in vogue certainly since the 14th c., when it was made and sold in Paris, according to Montell in his *Histoire des Français* (tom. ii. pp. 47, 48); it was then made of rye dough, kneaded with ginger and other spice, and honey or sugar. It was probably introduced to England by the court of Henry IV., and since that time has played an important part in the pleasures of young and old at the fairs and festivals of the country. Changes were no doubt wrought in its composition as soon as it appeared in this country, and the expensive honey gave way to the cheaper treacle which was then in use, and the colour was hidden under some colouring matter or gilding. 'To take the gilt off the gingerbread,' has become a proverb, and the booths glittering with their gilded array of rude devices in gingerbread, so familiar to our boyhood, still make an occasional appearance in the country fairs.

Three forms of this article are to be found in most pastry-cooks' shops, and one or more of them in the sanctum of every good housewife. 1. Square soft cakes, from two to three inches in thickness. 2. Thin cakes of various forms, but most frequently round, being stamped out with the top of a wine-glass, or other contrivance. 3. Small button-like cakes, called gingerbread-nuts. The two last should be baked very quickly, crispness being indispensable

GINGER-WINE—GINSENG.

The constituents of modern gingerbread are treacle, moist sugar, wheaten-flour, and butter; a little carbonate of magnesia and tartaric acid, or carbonate of ammonia, are also put in to give lightness by many makers.

GINGER-WINE, a popular and cheap liqueur, made by the fermentation of sugar and water, and flavoured with various substances, but chiefly with ginger. It is partly an article of domestic manufacture, and is partly made on a larger scale for sale. It may be made by dissolving about six pounds of sugar in fourteen gallons of water; adding four ounces of bruised ginger and the whites of two eggs, well beaten; mixing thoroughly; boiling for a quarter of an hour; skimming carefully; and when the liquor has cooled, adding the juice of four lemons, and also their rinds for flavouring, with a tea-cupful of ale-yeast to promote fermentation; letting it ferment in an open vessel for twenty-four hours, and then putting it into a cask of suitable size, closely bunged, in which it remains for a fortnight before it is bottled. It is, however, very common to increase the strength of ginger-wine by the addition of spirits, the flavour being also modified by the kind of spirits employed. A little spirits added makes ginger-wine keep well, and it even improves in quality for many months. Its quality depends much on that of the sugar and of the ginger employed, and also on the care with which the manufacture is conducted.

GINGHAM. A cotton fabric originally introduced with its present name from India; it is now manufactured to an immense extent in Britain, and our manufacturers supply, to a very great extent, the Indian markets. It differs from calico in the circumstance, that its colours are woven in and not afterwards printed. At first, the Indian gingham consisted of cotton cloths, with two or more colours arranged as a small checkered pattern; now, a great variety of designs are found in this material, and in the case of umbrella gingham, the whole piece is woven with yarn of one colour. The following are the chief kinds of gingham known in the markets of Great Britain: plain common light grounds; plain common dark grounds; Earleton gingham; power-loom seersuckers and checks (imitations of the Indian patterns); muslin ground (stripes and checks); furniture stripes and checks; coloured diapers; crossover stripes; derries, Hungarians; jean stripes, and umbrella gingham.

GINGILIE OIL, a name often given to the bland fixed oil obtained by expression from the seeds of *Seamum Indicum*. See **SEAMUM**.

GINGKO, or **GINKO** (*Salisburia adiantifolia*), a large tree of the natural order *Taxaceæ* (yew, &c.), with straight erect trunk and conical head, and leaves remarkably resembling the leaflets of the fronds of maidenhair, somewhat triangular, cloven and notched at the upper extremity, shortly stalked, leathery, smooth, shining, yellowish green, with numerous minute parallel ribs, and somewhat thickened margins. The fruit is a sort of drupe, of which the fleshy part is formed by the persistent calyx, about an inch in diameter; the nut or endocarp white, a thin shell with a farinaceous kernel resembling an almond in flavour, with a little mixture of austerity. The tree is a native of China, but has been long known in Europe, and large trees are now to be seen in England. The wood is easy to work, receives a fine polish, is yellowish white, veined, and not resinous. In China and Japan, the G. is grown chiefly for the kernel, which is freed from austerity by boiling and roasting. The fleshy part of the fruit, although resinous and astringent, is also eaten

after being slightly roasted. The male and female flowers are on different trees, but the Chinese plant

Ginkgo Tree :

a, branchlet of female tree; b, branchlet of male tree, in flower; c, male flowers; d, female flowers; e, fruit; f, anther.

several close together, which grow into a monstrous tree, producing both male and female flowers.

GINSENG, a root highly esteemed in China as a medicine, being universally regarded as possessing the most extraordinary virtues, and as a remedy for almost all diseases, but particularly for exhaustion of body or mind. It is sometimes sold for its weight in gold. It was once introduced into Europe, but soon forgotten. It is the root of a species of *Panax*, of the natural order *Araliaceæ*, to which the name *P. Ginseng* has been given, and which is a native of Chinese Tartary; having a stem from one foot to two feet high; leaves on long stalks, five-fingered, and almost quite smooth; and umbels on a long terminal stalk. It is doubted by many botanists if

Ginseng (*Panax quinquefolium*).

this species is really distinct from *P. quinquefolium*, a common North American plant; the root of which is now an article of export from North America to China, and is used as a domestic medicine in the states west of the Alleghanies, but which European and American medical practitioners generally regard as almost worthless. It is mucilaginous, sweetish, and slightly bitter and aromatic.—*P. fruticosum* and

P. cochlearius as fragrant aromatics, growing in the Moluccas, and used by the native practitioners of India.—The fruit of the genus *Panax* is succulent, compressed, with two or three leathery one-seeded cells.

GIOBERTI, VINCENZO, a remarkable Italian writer and thinker of modern times, was born in 1801 at Turin. He was educated for the church, obtained his degree of doctor of theology in 1823, and was ordained to the priesthood in 1825. He was subsequently appointed professor of theology in the university of his native city, and on the accession of Charles Albert, was selected as chaplain to the court, an office which he filled with distinction till 1833. At this period of rising political agitation, G. was accused of promoting the liberal movement, was dismissed from court, and suffered an imprisonment of four months. Having obtained permission to retire into banishment, he went first to Paris, and shortly after to Brussels, where he spent eleven years as private tutor in an academy, pursuing in his leisure hours his private studies. A devout Catholic, G. looked upon the papacy as the divinely appointed agency for the elevation of Italy among the nations. A confederation of states subject to papal arbitration, and having in the king of Piedmont a military protector, was the scheme devised by G. for the unity and regeneration of his country. In short, in the 19th c. he advocated the Guelph policy of the middle ages. These views he elaborately developed in his work entitled, *Il Primato Civile e Morale degli Italiani* (The Civil and Moral Supremacy of the Italians). Its publication in Paris in 1842, during the author's exile, was hailed with the utmost enthusiasm by Italy, with the exception of a limited and far-sighted section of the country. The liberal and conciliatory policy adopted by Rome on the accession of Pius IX., appeared the verification of G.'s predictions, and increased the popularity of his name. On his return to Italy, he was received with universal ovations from all classes of the people, and was honoured by being chosen by several towns as their representative in parliament. The king appointed him senator, he subsequently was elected president of the chamber of deputies, and finally prime minister; owing to the great divergence of opinion which divided his ministry, he held office only for a few weeks, and was forced to resign. His successor despatched him to Paris on some unimportant mission, in order it was thought to remove him from Turin; and thus ended G.'s political career, as from that period he filled no official position, but devoted himself exclusively to literary pursuits. As a politician, G. failed in far-sightedness; and with the course of events in Italy, his influence as a political guide inevitably declined; but the depth and range of thought and strength of conviction evinced in his various works, entitle him to the consideration and standing which as a writer he enjoys. G.'s remarkable gentleness in private intercourse bore no trace of the energetic force with which his writings propound an opinion or denounce an opponent. He died at Paris of apoplexy in 1853. His chief writings are entitled, *Introduzione allo studio della Filosofia* (Paris, 1839); *Il Primato* (Paris, 1842); *Il Gesuita moderno*, 8 vols. (Lausanne, 1847); *Il Rinascimento civile degli Italiani* (Paris, 1851).

GIOJA, the name of four towns of the south of Italy. The most important is in the province of Terra di Bari, 26 miles south of the town of Bari. It is a thriving industrious place, surrounded by a fine fertile territory. Pop. 14,000. It was formerly famous for the beauty of its woods, the favourite hunting-grounds of the Emperor Frederic II.

The second town is in the province of Calabria, Ultra I., situated a mile from the sea, and 28 miles north-east of Reggio. It is said to be of ancient origin, and has sustained several severe sieges. It was finally all but destroyed in 1783 by an earthquake, and now possesses only about 1000 inhabitants.—The third G. is in the province of the Abruzzi, Ultra II., 34 miles south-south-east of Aquila, and 60 from the sea, with 2409 inhabitants. Its territory, although mountainous, is productive.—The fourth is a town of 3560 inhabitants, in the province of Terra di Lavoro, 6 miles north-west of Cerreto.

GIOJA, MELCHIORRE, a famous Italian statistician, was born at Piacenza, 20th September 1767. He was educated for the priesthood, and for some time discharged the duties of tutor in a noble family, but through the liberality of his brother was enabled to resign this post, and to follow his own bent, which was towards social and economic science. When the invading forces of France descended into Italy, G. had already attracted much notice by his political writings; and in 1797 he quitted Piacenza for Milan, and was there appointed state historiographer, a post he was deprived of in 1803, in consequence of his work on divorce giving great dissatisfaction. In 1806, he was appointed director of the statistical department, and in 1809 the minister Vaccari intrusted to him the preparation of a grand statistical report of all Italy. This great labour was still in progress when a change of government interrupted it. G. died at Milan, January 2, 1829. His laborious habits and immense knowledge of the subjects he wrote upon, enabled him to accomplish an incredible amount of labour, but he is justly blamed for the bitter strain of personal invective with which he resented the least unfavourable criticism of his works. Some of his chief works are: *Sul Commercio de' Commestibili e caro prezzo del vitto* (Milan, 1802, 2 vols. in 12mo); *Teoria civile e penale del divorzio ossia necessità, cause nuova maniera di organizzarla* (Milan, 1803, in 8vo); *Nuovo prospetto delle scienze economiche, ossia somma totale delle idee teoriche e pratiche in ogni ramo d'amministrazione privata e pubblica* (Milan, 1815 to 1819, 6 vols. in 4to); *Filosofia della Statistica* (Milan, 1826, 2 vols. in 4to); *Dell'ingiuria, dei danni, del soddisfacimento e relative basi di stima* (Milan, 1802, 2 vols. in 8vo).

GIOJO'SA, a town of Naples, in the province of Calabria, is situated about 7 miles north-east of Gerace, in a fertile and beautiful district, and is supposed to have risen on the ruins of the ancient city of Mitra, mentioned by Pliny. Its air is remarkable for purity, and its inhabitants for physical vigour and beauty. Pop. estimated at 8485.

GIORDANO, LUCA, an Italian painter, was born of impoverished parents at Naples, about 1632; studied under Ribbiera or Spagnoletto, and made rapid progress. Singularly enough, considering his fine imagination and delicate touch, both his early productions as well as those of his more mature years, indicate rather a power of beautifully correct imitation, than any marked originality or elevation of genius. On leaving Ribbiera's school, G. repaired to Rome, where he became the scholar and fellow-worker of Pietro da Cortona. Subsequently, he went to Lombardy and Venice, to familiarise himself with the styles of the schools of art there. After some time he proceeded to Madrid, in 1692, at the request of Charles II., king of Spain, who desired his assistance in the embellishment of the Escorial. His pleasing freedom of manner and genial humour rendered him a special favourite during his residence at the Spanish court, which he only

quitted for Italy on the death of the king, ten years later. The extreme rapidity of execution for which G. was remarkable, enabled him to produce a prodigious number of works, but undoubtedly told detrimentally against their excellence. With some blemishes they possess, however, many beauties, and are chiefly admired for their spirited animation of character, and harmonious freedom of treatment, they also excel in boldness and perfection of the foreshortening. The palaces Riccardi and Pitti contain some fine specimens of this artist's style, but his best paintings are in the galleries of Dresden and Naples, and the Escorial at Madrid. G. died about 1704. The name of *Fa presto*, which distinguished him through life, referred to his father's incessant injunction to *work quickly*, in order that the proceeds of his labour might relieve the indigence of the family.

GIORGIONE, or GIORGIO BARBARELLI, one of the most poetical and fascinating of Italian painters, was born about 1478 at Castelfranco, in the Venetian territory of Trevisano. He studied under Giovanni Bellini, but quickly surpassed his master; for while Bellini's style is distinguished for its minute finish and cramped precision, that of G. literally revels in freedom and breadth of outline, and gorgeous depth of colour. Unfortunately for art, G. died in 1511, at the early age of 33. His works are of course limited in number, but they are among the most rare and exquisite examples of the Venetian school. Scriptural scenes, highly original in idea and treatment, portraits, and a few sweet idyllic scenes, representing pastoral concerts and sylvan enjoyments, form the subjects of these pictures, which all glow with the fine imagination, the rich colouring, and the energy of touch, that are G.'s distinctive attributes. The Lombard galleries and the Louvre possess the best authenticated originals of G., whose imitators were numerous.

GIOTTO, or AMBROGIOTTO BORDONE, a great painter, architect, and sculptor, born in 1276, was the son of a poor shepherd, and passed the earliest years of his life in watching flocks in his native Tuscan valley of Vespignano. Here he first essayed to reproduce on a fragment of slate the forms of nature surrounding him, and to the subtle influences of these early associations may be ascribed much of the devotion which G.'s perfected works evince towards nature in her purest and most winning aspects. One of these simple designs, representing a sheep, having fallen under the notice of Cimabue, the latter became interested in G., and having obtained the consent of the youth's father, received him into his studio. G.'s intuitive perception of the *true* in art speedily emancipated him from the conventionalities, although it is true that Cimabue himself had previously taken steps in this direction. In G.'s paintings, however, we first markedly observe instead of the flat elongated forms and lifeless features of the Byzantine types, figures imbued with the varied action and expression of nature, and exhibiting besides an ideal elevation and grandeur of character. He first also practised the art of grouping with due regard to the sentiment and action of the composition, and gave simplicity and grace to the draping outline; in short, he effected a profound reformation in the style of art, which from his era assumed its rightful alliance with the beautiful in nature. G. was also an eminent architect, and was employed in the execution of the dome of Florence, while from his designs the Campanile (q. v.) was built. The beloved friend of Dante, and of all the great souls of his age, he himself presented a rare union of genius, knowledge, and wit, combined with the utmost

equanimity of humour and massive good sense. The restorer of portraiture, his pencil has transmitted to our day the features and personality of his cherished Dante, of Brunetto Latini, Corso Donati, and other celebrities; and in return we find his name enshrined with reverence in all the grand literary works of the times, especially in those of Dante, Boccaccio, and Petrarca. The works of this illustrious man are too numerous to be recorded here, but we may mention some of the principal. 'The Coronation of the Virgin,' in the church of Santa Croce at Florence; 'A Last Supper,' in the refectory; the famous mosaic, executed at Rome for Pope Boniface VIII., named 'La Navicella,' and representing Peter walking on the waves, a wonderful work, which has unhappily severely suffered in the successive repairs it has required; the frescoes of the 'Seven Sacraments,' painted at Naples in the church of the Incoronata, one of the most perfect of his works in point of preservation; and the frescoes of Assisi, illustrating the life of St Francis, and innumerable other minor works. G. died at Florence in 1336, and was interred in the church of Santa Maria del Fiore, where a marble monument was erected to his honour by Lorenzo de' Medici.

GIOVA'NNI (SAN) A TEDUCCIO, a town of 7298 inhabitants, three miles east of Naples, is situated near the sea-shore in a fertile plain. Its neighbourhood is well cultivated, and embellished with beautiful villas. Its origin is supposed to be very ancient, and its name is attributed to the Emperor Theodosius, whose name is carved on a small ancient column discovered in the vicinity of the town.

GIOVENAZZO, a thriving little town in the south of Italy, province of Terra Di Bari, is situated on the shore of the Adriatic, 14 miles west-north-west of the town of Bari. It is considered the Natiolum of the Romans, and possesses some remains of its ancient walls. In the 11th c. it belonged to the Greeks, and eventually passed into the possession of the Gonzaga family. There is here an excellently organised asylum for the poor, conjoined with extensive juvenile reformatories. G. is encircled by vineyards and rich plantations of olive, almond, and other fruit-bearing trees. Pop. upwards of 7000.

GIPSIES. See **GYPSIES**.

GIRAFFE, or CAMELOPARD (Camelopardalis Giraffa), the tallest of quadrupeds, ranked by some naturalists among deer (*Cervidae*), but more properly regarded as constituting a distinct family of ruminants, which contains, however, only one species. It is a native of Africa, from Nubia to the Cape of Good Hope, extensively diffused, but apparently nowhere abundant. It occurs generally in small herds of from five to forty. It feeds on the leaves and small branches of trees. Its general aspect is remarkable from the height of the foreparts and great elongation of the neck, the head being sometimes 18 feet from the ground. The number of vertebrae in the neck, however, is not greater than in other quadrupeds, and it has no extraordinary flexibility, although its form and movements are very graceful. The body is short, and the back slopes from the shoulder to the tail; but the greater height of the foreparts is not owing, as has been often alleged, to the greater length of the fore-legs, which are not really longer than the hind-legs, but to processes of the vertebrae, which form a basis for the muscular support of the neck and head. The articulation of the skull to the neck is such that the head can be easily thrown back until it is in the same line with the neck, thus giving the animal additional power of reaching its

appropriate food. The skull has empty cavities, which give lightness to the head, along with sufficient extent of surface for the insertion of the ligament which supports it. The legs are long and slender; the feet have cloven hoofs, but are destitute of the

been supposed to be the armor of the Jews, translated *chamosis* in the English Bible (Deut. xiv. 6). In the year 1836, giraffes were added to the collection in the Zoological Gardens of London, and interesting opportunities of studying their habits have since been enjoyed. They are fed chiefly on hay placed in high racks, greatly enjoy carrots and onions, and a lump of sugar is a favourite delicacy. They have bred in England. The flesh of the G. is said to be pleasant, and its marrow is a favourite African delicacy.

GIRALDUS CAMBRENSIS, the literary name of Gerald de Barri. He was fourth son of William de Barri, a Norman noble who had settled in Pembrokeshire, and allied himself by marriage to the family Rhys ap Theodor, prince of South Wales. G. was born about 1146, and educated by his uncle David, who was Bishop of St David's. He entered the university of Paris in his 20th year, and after three years of much literary distinction he returned to England, entered into holy orders in 1172, and was soon afterwards appointed Archdeacon of St David's. He was from the first a zealous churchman; strenuous in the enforcement of discipline, and especially of clerical celibacy; and was the chief agent in the establishment of the payment of tithes within the principality. On the death of his uncle, the chapter of St David's elected him bishop; but as the election was made without the royal licence, G. renounced it. The king, Henry II., directed a new election; and on the chapter's persisting in their choice of G., the king refused to confirm the selection, and another bishop, Peter de Leia, was appointed. G. withdrew for a time to his old residence in the university of Paris, and on his return he was required, by the Archbishop of Canterbury, to take the administration of the diocese of St David's, which had utterly failed in the hands of De Leia. He held it for four years, when being appointed a royal chaplain, and afterwards preceptor to Prince John, he accompanied that prince in 1185 in his expedition to Ireland, where he remained after John's return, in order to complete the well known descriptive account of that country, which, although very valuable as a whole, has in many of its details called forth much angry criticism from Irish scholars and antiquaries. On his return, in 1187, he read this work publicly in the university of Oxford, giving a full day to each of the three divisions of which it consists. A tour of Wales which he made (1188) in the company of Baldwin, Archbishop of Canterbury, led to a similar descriptive work, the *Itinerarium Cambriae*. In the following year he accompanied the king to France, where he remained till the king's death. His later years, after his return, were full of disappointment. On the see of St David's again becoming vacant, he was again unanimously elected by the chapter; but the Archbishop of Canterbury having interposed, G., notwithstanding an appeal to Rome, in prosecuting which he made three different journeys in the course of five years of the contest, failed to obtain a confirmation of the nomination. He soon afterwards resigned his archdeaconry, and devoted the remaining seventeen years of his life to study. Once again the see of St David's became vacant, but although it was offered to G. on certain conditions, he declined to accept it, and died at St David's in the 74th year of his age. The reason why G.'s appointment to the bishopric was so much opposed is not clearly known, but the king, it is said, had resolved that no native of Wales should obtain the dignity. G.'s writings, although disfigured by credulity, and in the personal narratives with which they abound, by excessive vanity, are of great value as materials for the history, and

Giraffe.

small lateral toes or spurious hoofs, which occur in the other cloven-footed ruminants. The head is long; the upper lip entire, projecting far beyond the nostrils, and endowed with considerable muscular power. The tongue is remarkably capable of elongation, and is an organ of touch and of prehension, like the trunk of an elephant; it can be thrust far out of the mouth, and employed to grasp and take up even very small objects; it is said that its tip can be so tapered as to enter the ring of a very small key. The usefulness of such an organ for drawing in leaves and branchlets to the mouth is obvious. The G. adroitly picks off the leaves of acacias and other thorny plants, without taking the thorns into its mouth. The dentition of the G. agrees with that of antelopes, sheep, goats, and oxen; the upper jaw of the male is destitute of the canine teeth, which are present in the male of most kinds of deer. The head is furnished with two remarkable protuberances between the ears, generally described as horns, but very different from the horns of other animals, and each consisting of a bone united to the skull by an obvious suture, permanent, covered with skin and hair, and terminated by long hard bristles. There is also a projection on the forehead. The ears are moderately long; the tail is long, and terminates in a tuft of long hair that nearly reaches the ground. There is a callosity on the breast. The neck has a very short mane. The hair is short and smooth; the colour is a reddish white, marked by numerous dark rusty spots. The eye of the G. is very large and lustrous, and so placed that the animal can look all around without turning its head, so that in a wild state it is not easily approached. Its nostrils have a muscle by which they can be closed; a provision, as Owen supposes, for excluding particles of sand. It is an inoffensive animal, and generally seeks safety, if possible, in flight, although it is capable of making a stout resistance, and is said to beat off the lion. It fights by kicking with its hind-legs, discharging a storm of kicks with extraordinary rapidity. It is not easily overtaken even by a fleet horse, and has greatly the advantage of a horse on uneven and broken ground. Its pace is described as an amble, the legs of the same side moving at the same time. The G. was known to the ancients, and was exhibited in Roman spectacles. Representations of it appear among Egyptian antiquities. It has

for the social condition of the age and the countries which he describes. But they must be read with much caution, and with a careful critical consideration of the sources of the information which they embody. Several of his works are still preserved in manuscript in the British Museum, the Bodleian, the Lambeth, and Corpus Christi College Libraries. His printed works are the *Itinerarium Cambriae*; *Topographia Hiberniae*; *Expugnatio Hiberniae*; *Descriptio Cambriae*; and several smaller pieces, which are printed in the second volume of Wharton's *Anglia Sacra*. Barry's work on Ireland called out several rejoinders, the most valuable of which is that of John Lynch (under the pseudonym of *Gratianus Lucius*), entitled *Cambrensis Eversus*; a less valuable work is that of Stephen White, recently published, from the original manuscripts; Sir James Ware has freely criticised Barry in the *Antiquities of Ireland*.

GIRARDIN, EMILE DE, a French journalist and politician, the illegitimate son of the royalist general Alexandre de Girardin and Madame Dupuy, was born in Switzerland in 1802, educated in Paris, and in 1823 was appointed general secretary of the royal museums. After the July revolution, G. established the *Journal des Connaissances utiles*, for which he secured 120,000 subscribers; in 1832, the *Musée des Familles*; and in 1834, the *Almanach de France*. He also published an *Atlas de France* and an *Atlas Universel*. The whole of these publications were set forth as emanating from a *Société Nationale pour l'émancipation intellectuelle*, and were not without a considerable influence on the progress of public instruction in France. In 1836 he founded the *Presse*, as an organ of political conservatism, and soon found himself entangled in violent controversies. One of the unfortunate results of these was his duel with Armand Carrel, editor of the *National*, in which the latter fell. From this time onward to the Revolution of 1848, he was ardently occupied with politics both as a journalist and deputy; and from being a defender of Guizot and moderate liberalism, he became a decided republican.

G. was the first to propose Louis Napoleon as a candidate for the Presidency, but only four weeks after the triumph of the latter, he opposed him with the greatest virulence—the reason generally given, being that the President had shewn himself unwilling to agree to the political scheme submitted to him by his advocate. G. now threw himself into the arms of the Socialists. In 1856, he sold his share of the *Presse*, being unable to submit to the restrictions on journalism. G. is regarded as one of the ablest, though at the same time, one of the most turn-coat journalists in France. He is very fertile and original in his political ideas, which he has given to the world in a host of brochures.—MADAME DE GIRARDIN, wife of the preceding, whose maiden name was Delphine Gay (born 26th January 1804, died 29th June 1855), enjoyed during her lifetime a brilliant reputation as a poetess, novelist, and play-writer. Her best known work is her *Lettres Parisiennes*, which appeared in her husband's periodical *La Presse*, under the pseudonym of Le Vicomte de Launay.

GIRARDIN, ST MARC, an eminent French journalist and professor, born at Paris in 1801. He studied at the Collège Napoléon and the Collège Henri IV. with brilliant success, and in 1827 obtained a professorship in the Collège Louis-le-Grand. During a visit to Germany in 1830, he formed a close intimacy with Gans and Hegel, and on his return to Paris, was appointed to succeed Guizot as professor of history in the Faculty of Letters, and was named master of requests to the Council of State.

In 1834 he was called to the chair of poetry at the Sorbonne. About the same time he was elected a member of the Chamber of Deputies, and acquired a considerable reputation by his report upon the organisation of secondary instruction presented in 1837. In 1844 he was received into the *Académie*. G. took no special part in the Revolution of 1848, and still continues his functions as professor at the Sorbonne. His influence and popularity as a lecturer are very great. Clearness, good sense, moderation, vivacity, and humour are his leading characteristics. Besides his numerous contributions to the *Débats*, which he has partly edited since 1827, and to the *Revue des Deux Mondes*, he has published several large works, among which may be mentioned *Notices Politiques et Littéraires sur l'Allemagne* (1834); *Cours de Littérature Dramatique* (4 vols. 1843); *Essais de Littérature et de Morale* (2 vols. 1844); and *Tableau de la Littérature au 16th Siècle, suivi d'Études sur la Littérature du Moyen Âge et de la Renaissance* (1862).

GIRASOL, a precious stone, exhibiting in strong lights a peculiar and beautiful reflection of bright red or yellow light, which seems to come from the interior of the stone. From this it derives its name (Ital. 'sun-turning'). There are different kinds of G., variously referred by mineralogists to quartz and opal, species which, however, are very nearly allied. One kind is also known as *Fire Opal*, which is found only at Zimapan, in Mexico, and in the Faroe Islands. The Mexican specimens are of a rich topaz yellow colour, and the reflection is very bright. Another kind is the *Quartz Resinite* of Hally, so called because of its characteristic resinous fracture. It is found of various colours, sometimes of a fine yellow or emerald green, more generally bluish white. For a specimen of extraordinary brilliancy, not an inch and a half in diameter, £1000 has been refused. The ancients held this stone in high estimation. They called it *Asteria* (Gr. *aster*, a star). They obtained it both from Caramania and from India. The Caramanian stones were preferred. The brightest are at present brought from Brazil, but fine specimens are also brought from Siberia. Imitation girasols are made of glass, in which a little oxide of tin is mixed.—The name G. is sometimes given to a kind of sapphire, also called *Asteria sapphire*, exhibiting a similar reflection of light, and sometimes to *Sunstone*, an aventurine felspar.

GIRDER, a main beam used to support joisting walls, arches, &c. Girders may be of wood or iron, and are now very commonly made of cast iron. They are much used in supporting the upper walls of houses, while the lower part is cut away to allow of rearrangement. Wooden girders are sometimes strengthened with iron trusses, and are then called trussed girders. Sometimes a beam is cut in two, and an iron plate inserted between the pieces, and the whole bolted together. This kind of girder is called a sandwich beam. Girders are much used in railway works, in which case they are generally of wrought iron. The Menai and Britannia Bridges are simply very large boxed girders. The *lattice girder* is another form in which the sides are made somewhat like wooden lattice-work. See *STRENGTH OF MATERIALS*.

GIRDLE OF VENUS (*Cestum Veneris*), a very remarkable animal, one of the *Acalephas* (q. v.), inhabiting the Mediterranean, gelatinous, of a ribbon-like shape, sometimes five or six feet in apparent length by about two inches in breadth; although considered with reference to the structure of the animal, the apparent length is really its breadth, and the apparent breadth its length. The mouth is

situated in the middle of the inferior edge, and the stomach is imbedded in the gelatinous substance. The edges are fringed with cilia, by the movements

Girdle of Venus (*Cestum Veneris*).

of which the creature seems to be propelled in the water. It exhibits lovely iridescent colours by day, and brilliant phosphorescence by night. Its substance is so delicate, that a perfect specimen can with difficulty be obtained.

GIRGEH, the third largest town of Egypt, is situated on the left bank of the Nile, in lat. $28^{\circ} 20' N.$, and long. $31^{\circ} 58' E.$ It was here that the discontented Mamelukes rallied against Mohammed Ali. It contains eight handsome mosques, a large bazaar, and a cotton manufactory. The population is about 10,000, of whom 800 are Christians, and it has a convent of Catholic missionaries.—Clot Bey, *Aperçu Générale sur l'Egypte*, i. p. 214.

GIRGENTI. See **AGRIGENTUM**.

GIRL, in Heraldry, is the term used to signify the young of the roe in its second year.

GIRNAR, a sacred mountain in India of most remarkable aspect, stands in the peninsula of Kattywar, which forms part of the native state of Guzerat, in lat. $21^{\circ} 30' N.$, and long. $70^{\circ} 42' E.$ Above the mass of luxuriant hills and valleys which surround its base, rises a bare and black rock of granite to the height of about 3000 feet above the sea. The summit is broken into various peaks, its northern and southern sides being nearly perpendicular. An immense boulder, which seems to be poised on one of the scarped pinnacles, is called the Beiru Jhap, or Leap of Death, from its being used by devotees for the purpose of self-destruction.

GIRONDE, a maritime department in the south-west of France, is formed out of part of the old province of Guienne, and is bounded on the W. by the Bay of Biscay, on the N. by the department of Charente-Inférieure, on the E. by those of Dordogne and Lot-et-Garonne, and on the S. by that of Landes. It has an area of 4132 square miles, and a population of 640,757. It is watered mainly by the Garonne and the Dordogne, and by the Gironde, which is formed by the union of these two rivers. The surface of the land is in general flat; but in the east there are some hills. The climate is temperate, and except in the Landes or sandy tracts, which, however, occupy nearly all the western half of the department, is healthy. In the east and north-east the soil is chiefly calcareous. Wine, including the finest clarets, is the great product of the department. The principal growths are those of Laïtte, Latour, Château-Margaux, Haut-Brion, Sauterne, Barsac, and the Vins de Grave, and the quantity produced annually averages 44,000,000 gallons. Grain, vegetables, fruit, and hemp are also produced largely. On the west coast, on the downs or sand-hills, there are extensive plantations of pine, from which turpentine, pitch, and charcoal are obtained. The shepherds of the Landes traverse the sands on high stilts, and travel with them also to markets and

fairs. Among the manufactures, salt, calico, muslin, chemical products, pottery, paper, vinegar, and brandy, are the chief. Bordeaux is the capital.

GIRO'NDISTS (Fr. *Girondins*), the name given during the French Revolution to the moderate republican party. When the Legislative Assembly met in October 1791, the Gironde department chose for its representatives the advocates Vergniaud, Guadet, Gensonné, Grangeneuve, and a young merchant named Ducos, all of whom soon acquired great influence by their rhetorical talents and political principles, which were derived from a rather hazy notion of Grecian republicanism. They were joined by Brissot's party and the adherents of Roland, as well as by several leaders of the Centre, such as Condorcet, Fauchet, Lasource, Isnard, and Henri La Rivière, and for some time had a parliamentary majority. They first directed their efforts against the reactionary policy of the court, and the king saw himself compelled to select the more moderate of the party, Roland, Dumouriez, Clavière, and Servan, to be ministers. Ultimately, however, he dismissed them, a measure which led to the insurrection of the 20th June 1792. The encroachments of the populace, and the rise of the Jacobin leaders, compelled the G. to assume a conservative attitude; but though their eloquence still prevailed in the Assembly, their popularity and power out of doors were wholly gone, and they were quite unable to prevent such hideous crimes as the September massacres. The principal things which they attempted to do after this—for they never succeeded in accomplishing anything—were to procure the arrestment of the leaders of the September massacres, Danton, &c.; to overawe the mob of Paris by a guard selected from all the departments of France; to save the king's life by the absurdest of all possible means, viz., by first voting his death, and then by intending to appeal to the nation; and, finally, to impeach Marat, who, in turn, induced the various sections of Paris to demand their expulsion from the assembly and their arrestment. This demand, backed up as it was by 170 pieces of artillery under the disposal of Henriot (q. v.), leader of the sans-culottes, could not be resisted; thirty of the G. were arrested on a motion of Couthon, but the majority had escaped to the provinces. In the departments of Eure, Calvados, and all through Brittany, the people rose in their defence, and under the command of General Wimpfen, formed the so-called 'federalist' army, which was to rescue the republic from the hands of the Parisian populace. Movements for the cause of the G. took place likewise at Lyon, Marseille, and Bordeaux. The progress of the insurrection was, however, stopped by the activity of the Convention. On the 20th July, the revolutionary army took possession of Caen, the chief station of the insurgents, whereupon the deputies of the Convention, at the head of the sans-culottes, forced their way into the other towns, and commenced a fearful retribution.

On the 1st October 1793, the prisoners were accused before the Convention by Amar, as the mouthpiece of the Committee of Public Safety, of conspiring against the republic with Louis XVI., the royalists, the Duke of Orleans, Lafayette, and Pitt, and it was decreed that they should be brought before the Revolutionary Tribunal. On the 24th, their trial commenced. The accusers were such men as Chabot, Hébert, and Fabre d'Eglantine. The G., however, defended themselves so effectually, that the Convention on the 30th was obliged to come forward and decree the closing of the investigation. That very night, Brissot, Vergniaud, Gensonné, Ducos, Fonfrède, Lacaze, Lasource, Valazé, Sillery,

Fauchet, Duperret, Carra, Lehardy, Duchâtel, Gardien, Boileau, Beauvais, Vigée, Duprat, Mainvielle, and Antiboul, were sentenced to death, and, with the exception of Valazé, who stabbed himself on hearing his sentence pronounced, all perished by the guillotine. On their way to the Place de Grève, in the true spirit of French republicanism, they sang the *Marseillaise*. Coustard, Manuel, Cussy, Noël, Kersaint, Rabaut St Etienne, Bernard, and Mazuyer, were likewise afterwards guillotined. Biroteau, Grangeneuve, Guadet, Salles, and Barbaroux ascended the scaffold at Bordeaux; Lidon and Chambon, at Brives; Valady, at Périgueux; Dechézeau, at Rochelle. Rebecqui drowned himself at Marseille, Pétion and Buzot stabbed themselves, and Condorcet poisoned himself. Sixteen months later, after the fall of the Terrorists, the outlawed members, including the G. Lanjuinais, Defermon, Pontécoulant, Louvet, Isnard, and La Rivière, again appeared in the Convention. A rather flattering picture of the party has been drawn by Lamartine, in his *Histoire des Girondins* (8 vols., Paris, 1847).

GIRONNÉ, GYRONNÉ, GYRONNY (Latin, *gyrus*, a circle), terms used in Heraldry to indicate that the Field (q. v.) is divided into six, eight, or more triangular portions, of different tinctures, the points of the triangles all meeting in the centre of the shield. Nisbet (i. 28) objects to this as a vulgar mode of blazoning, and, in speaking of the 'paternal ensign of the ancient surname of Campbell,' he says (p. 31) that it is 'composed of the four principal partition lines, parti, coupé, traunché, taillé, which divide the field into eight gironal segments, ordinarily blazoned with us girony of eight, or, and sable.' The triangle in dexter-chief has been called a Giron or Gyron.

GIRVAN, a seaport town and burgh of barony, on the west coast of Scotland, is beautifully situated at the mouth of the river Girvan, in the county of Ayr, and about 21 miles south-west of the town of that name. It is now the terminus of the Glasgow and South-Western Railway, and owns considerable tonnage in shipping. The harbour has been much improved of late, and a considerable trade, especially in the shipment of coal, is carried on betwixt G. and Belfast, from which it is distant about 65 miles. The valley of the Girvan is one of the most beautiful and best cultivated districts in the south-west of Ayrshire, and abounds with coal, lime, and ironstone. The land is of the richest description. The town is situated opposite the celebrated 'Ailsa Craig,' and has been much frequented of late in the summer season by parties in quest of sea-bathing, for which the coast is admirably adapted. Pop. (1861) 7047.

GISORS, a town of France, in the department of Eure, situated on the river Epte, 33 miles north-east of Evreux, and on the high-road from Paris to Rouen. Pop. 3245. Here a battle took place, 10th October 1198, between the French and English, in which the former were completely defeated. Richard I., who commanded the English, gave, as the 'parole,' or watchword of the day, *Dieu et mon Droit* (God and my Right), and ever since, the expression has been the motto to the royal arms of England.

GIULINI, GIORGIO, a learned historian and antiquary, was born at Milan in 1714. He studied law at the university of Padua, and received the degree of Doctor at an early age. G. devoted his decided antiquarian genius to researches into the monuments and remains of his native land; and after twenty years of patient labour, he published a valuable historical work, entitled *Memoirs concerning the Government of Milan, with*

Description of the City and Milanese Territory from the Early Ages. These Memoirs, in 4 vols., embrace the period from the destruction of the Lombard domination, or establishment of the Franks in Italy, down to the opening of the 14th century. In three subsequent books, he descends to 1447, when the House of Visconti was elevated to sovereign rule in Milan. The work is considered by G.'s countrymen a master-piece of learning, impartiality, and judgment. Much of the history is based upon the evidence of coins, seals, documents, and monuments of the various ages. Milan proudly recognised G.'s patriotic labour by appointing him state historian, and, at the request of the Empress Maria-Theresa, he collected materials for four additional books, with the view of bringing the work down to the 16th century. Before achieving this design, he died of apoplexy on Christmas Eve, in 1780. G. was distinguished for active benevolence as well as learning. He likewise cultivated with enthusiasm both poetry and music.

GIULIO PIPPI, surnamed 'ROMANO,' from the place of his birth, was born at Rome in 1492, and became one of Raphael's most distinguished and beloved pupils. His excellence as an architect and engineer almost equalled his genius as a painter. G. assisted Raphael in the execution of several of his finest works, and by special desire of the great master, he was intrusted with the completion of all his unfinished designs after his death. He likewise inherited a great portion of Raphael's wealth. The works executed by G., in imitation of Raphael, reflect so wonderfully, not alone the style and character, but the sentiment and spirit of the original, that in many instances uncertainty has arisen as to the hand from which they emanated; while, on the contrary, the more original creations of G. are deficient in the ideal grace of his master, and display rather breadth, and power of treatment, and boldness of imagination, than poetical refinement or elevation. Unlike Raphael, the chief excellence of G. does not lie in his conception of the divine or Christian, but rather of the classical ideal. G. died in 1546.

The principal architectural works designed by G. were executed at Mantua, during his lengthened residence at the court of Duke Frederick Gonzaga. The drainage of the marshes surrounding Mantua, and the securing the city from the frequent inundations of the rivers Po and Mincio, attest his skill as an engineer; while his genius as an architect found free scope in the restoration and adornment of many of the chief public edifices of Mantua, and especially in the erection of the splendid palace known as Il Palazzo del Te, which he also embellished with mythological frescoes, and a profusion of exquisite decorations. Many of G.'s finest pictures passed into the possession of Charles I. of England, who purchased, in 1629, the celebrated collection of the Dukes of Mantua. Several of them are now contained in the Hampton Court Gallery; but the finest of all, a 'Nativity,' was sold to France, and now adorns the Louvre. The Naples gallery of Capi d'Opera possesses a Holy Family by G., called the 'Madonna della Gatta,' and considered the greatest of his pictures; it is strongly imbued with the spirit and influence of Raphael. The Loggia of Raphael, in the Vatican, also contains some fine frescoes executed by G.; and in the Palazzo Farnese there is a grand frieze attributed to him.

GIURGEVO, an important trading town of Wallachia, is situated on the left bank of the Danube, directly opposite Rustchuk, and 40 miles south-south-west from Bucharest, of which town

it is the port. It was originally the Genoese settlement of St George. It is the great landing-place for steamers in Wallachia. A bridge across a narrow channel connects G. with Slobodse, an island in the Danube, on which stands a fortified castle. Here the Turks defeated the Russians, 7th July 1854. Pop. 20,000.

GIUSTI, GIUSEPPE, the most celebrated and popular of the modern poets and satirists of Italy, was born in 1809, at Pescia, in the vicinity of Florence. Sprung from an influential Tuscan family, G. was early destined to the bar, and at Pistoja and Lucca commenced the preliminary studies, which were completed at the university of Pisa, where he obtained his degree of Doctor of Laws. Sustained earnestness of study seems to have formed no feature in G.'s collegiate course, whose natural bent rather inclined him to a genial participation in the freaks and social pleasures of his companions than to the erudite investigation of the Pandects. On quitting Pisa, G. was domiciled at Florence with the eminent advocate Capoquadri, who subsequently became Minister of Justice, and here he first attempted poetry. Lyrical compositions of the romantic school, evincing both elevated and nervous thought, were his earliest efforts; but he speedily comprehended that satire, not idealism, was his true forte. In a pre-eminent degree, G. possesses the requirements of a great lyrical satirist—terse, clear, and brilliant, he depicts, alternately with the poignant regret of the humanitarian, and the mocking laugh of the ironist, the decorous shams and conventional vices of his age. His impartiality only lends a keener sting to his denunciation. The stern flagellator of tyrants, he is no less merciless in stigmatising those whose pliant servility helps to perpetuate the abasement of their country. Nor does he adulate the people, whose champion he avowedly is, and whose follies and inconsistencies he indicates with the faithfulness of a watchful friend. The writings of G. exercised a positive political influence. When the functions of the press were ignored, and freedom of thought was treason, his flaming verses in manuscript were throughout all Italy in general circulation, fanning the hatred of foreign despots, and powerfully assisted in preparing the revolutionary insurrection of 1848. Then, for the first time, did G. discard the pseudonym of 'The Anonymous Tuscan,' and append his name to a volume of verses bearing on the events and aims of the times. All his compositions are short pieces, rarely blemished with personalities, and written in the purest form of the popular Tuscan dialect. The elegant familiarity of idiom which constitutes one of their chief and original beauties in the eyes of their native readers, presents great difficulties to foreigners, and still greater to the translator. G.'s writings are not only Italian in spirit and wit, but essentially Tuscan. A reverent student of Dante, G. himself often reaches an almost Dantesque sublimity in the higher outbursts of his scornful wrath, while he stands alone in the lighter play of ironical wit. In politics, an enlightened and moderate liberal, averse alike to bureaucracy and mobocracy, G. was also beloved in private life for his social qualities, and his loving and gentle spirit. He died in 1850, aged 41, in the dwelling of his attached friend, the Marquis Gino Capponi, at Florence; and the throng of citizens who followed him to the grave, in the teeth of Austrian prohibition, attested eloquently the repute he enjoyed in life. His most celebrated pieces are entitled *Stivale*, or the History of a Boot (Italy), a humorous narration of all the misfits, ill-usage, and patching allotted to this unfortunate down-trodden

symbol of his country; *Gingillino*, a master-piece of sarcasm, portraying the ignoble career of the sycophant, whose supple back and petty diplomacy finally secure for him the highest distinctions; *Il Re Travicello*, or King Log, the subject of which is indicated by the title; *Il Briadisi di Girella*, or the Weathercock's Toast, one of his best pieces, dedicated to the suggestive name of Talleyrand; and the *Dies Irae*, or Funeral Oration of the Emperor Francis I. The only authorised and correct edition of his works is that published at Florence in 1852 by Le Monnier.

GIUSTINIANI, an illustrious Italian race, to which the republics of Venice and Genoa owed more than one doge. One of the palatial residences of Rome was erected towards the end of the 16th c. by a descendant of the family, the Marquis Giustiniani. The site he selected for the palace was a portion of the ruins of Nero's baths, and on its completion he enriched it with a magnificent private gallery of paintings, and a fine collection of sculptures. He also formed a museum of antiquities, the treasures of which were discovered on the spot. In 1807, the G. family conveyed the collection of paintings to Paris, where they disposed of the greater part by auction, and privately sold the remainder, consisting of 170 fine paintings, to the artist Bonnechose, who, in his turn, resold them to the king of Prussia. This fragment of the famous Giustiniani Gallery now enriches the Berlin Museum, and a very few of its former treasures are still to be found in the Giustiniani palace at Rome.

GIVET, a town of France, and a fortress of the first rank, is situated in the department of Ardennes, on both banks of the Meuse, close to the border of Belgium, and 145 miles north-east of Paris. The town consists of three districts—Charlemont, Givet St Hilaire, and Givet Notre Dame, all lying within the line of the fortifications. It is well situated in a commercial point of view, is regularly built, has handsome squares, a good port, barracks, a military hospital, and manufactures of leather, for which G. is famous, of white-lead, clay-pipes, sealing-wax, and nails; breweries, marble-works, and a zinc and copper foundry are also carried on. Pop. 4136.

GIVORS, a town of France, in the department of Rhone, is situated on the right bank of the river of that name, 14 miles south of Lyon. Bottles and window glass are here extensively manufactured, and a trade in ironstone and coal is carried on. Pop. 8578.

GLACIER is a name given to immense masses of ice, which are formed above the snow-line, on lofty mountains, and descend into the valleys to a greater or less distance, often encroaching on the cultivated regions. The materials of the glaciers are derived from the snow which falls during summer as well as winter on the summits of high mountains. Every fresh fall of snow adds a little to the height of the mountain, and, were there no agents at work to get rid of it, the mountains would be gradually rising to an indefinite elevation. Avalanches and glaciers, however, carry the snow into warmer regions, where it is reduced to water; in the one, the snow slips from the steep mountain slopes, and rushes rapidly down; in the other, it gradually descends, and is converted into ice in its progress. The snow which forms the glacier at its origin has a very different appearance and consistence from the ice of which it consists at its lower termination. The minute state of division of the ice, in its snow condition, and the quantity of air interspersed through it, gives it its characteristic white colour. Two causes operate in causing the change into ice: first, pressure expels the air by

bringing the particles of the lower layers of snow more closely together; and second, the summer's heat melting the surface, the water thus obtained percolates through the mass beneath, and as it passes amongst the particles whose temperature is below 32° F., it increases their size by external additions till the particles meet, and the whole becomes a solid mass. The snowy region of the

Glacier on the Alps.

glacier is called by the French name *névé*. In large glaciers, the *névé* is of great extent, a large quantity of material being required to make up the waste. The *névé* is, however, often confined to narrow valleys, and, as a consequence, produces glaciers which soon perish. The increase of a glacier by snow falling on its surface takes place only above the snow-line—below that line, all the accumulated winter's snows are speedily melted by the summer's heat. The ice of the glacier seldom exhibits any traces of the horizontal stratification which is found in the *névé*, but is generally intersected with vertical veins of clear blue ice.

The most remarkable feature of glaciers is their motion. It has been long known to the natives of the Alps that they move, but it is only within the last few years that it has received due attention from scientific men; the account of their observations, and the theories based upon them, form one of the most interesting chapters in the history of glaciers. See the writings of Agassiz, Forbes, and Tyndall. The continual waste of glaciers below the snow-line, both along its surface and at its extremity, is ever being repaired, so that the glacier does not recede from the valley, nor decrease in depth. That the materials of the reparation are not derived from the fall of the winter's snow, and the influence of the winter's frost, is evident, inasmuch as these additions speedily disappear with the return of the summer's heat, and in the end form but a small proportion of the year's total loss. The true repairing agent is the motion of the glacier, which brings down the glacified snow from the upper regions to be melted below. To account for this motion, Charpentier supposed the water which saturated the glacier in all its parts, and filled the innumerable capillary fissures, was, during night and during the winter, frozen, and that the well-known and almost irresistible expansion which would take place in the conversion of the water into ice, furnished the force necessary to move the glacier forwards. This theory, known as the *dilatation theory*, was for some time adopted by Agassiz, but ultimately abandoned. Agassiz shewed that the interior of the glacier had a temperature of 32° F., and subsequent observations have shewn that the glacier moves more rapidly in summer than in

winter. In 1799, De Saussure published a second theory, known as the *gravitation or sliding theory*, in which he supposed that the glacier moved by sliding down the inclined plane on which it rested, and that it was kept from adhering to its bed, and sometimes even elevated by the water melted in the contact of the glacier with the naturally warmer earth. While correctly attributing the motion to gravity, De Saussure erred in considering glaciers as continuous and more or less rigid solids—indeed, the motion he attributes to them would, if commenced, be accelerated by gravity, and dash the glacier from its bed as an avalanche. Principal Forbes was the author of the next important theory. Considerable attention had in the meantime been paid to the subject by Rendu, Agassiz, and others. Rendu had shewn that the glacier possessed a semi-fluid or river-like motion, in explaining the difference between observations made by him at the centre, which 'moves more rapidly,' and others made at the sides, 'where the ice is retained by the friction against its rocky walls.' The results based on Rendu's observations were established by the repeated and exact measurements of Forbes, who, in the progress of his examinations, made the further discoveries, that the surface moves more rapidly than the ice near the bottom, and the middle than the sides; that the rate of motion is greater where the glacier-bed has the greatest inclination; and that the motion is continued in winter, while it is accelerated in summer by the increase of the temperature of the air. The only theory which, as it appeared to Forbes, could account for these phenomena is thus expressed by him: 'A glacier is an imperfect fluid or a viscous body, which is urged down slopes of a certain inclination by the mutual pressure of its parts.' This is known as the *viscous theory*. He considered a glacier as not a crystalline solid, like ice tranquilly frozen in a mould, but that it possessed a peculiar fissured and laminated structure, through which water entered into its intrinsic composition, giving it a viscid consistence, similar to that possessed by treacle, honey, or tar, but differing in degree. Professor Tyndall has published another theory, which he designates the *pressure theory*. This differs little from that of Forbes, except that it denies that glacier ice is in the least viscid. By a number of independent observations, he established the facts first noticed by Rendu and Forbes, and added the important one, that the place of greatest motion is not in the centre of the glacier, but in a curve more deeply sinuous than the valley itself, crossing the axis of the glacier at each point of contrary flexure—in fact, that its motion is similar to that of a river whose point of maximum motion is not central, but deviates towards that side of the valley towards which the river turns its convex boundary. This seems a further corroboration of the viscous theory, but Tyndall explained it and the other facts by a theory which, while maintaining the quasi-fluid motion of the glacier, denied that this motion was owing to its being in a viscous condition. The germ of his theory, as he tells us, was derived from some observations and experiments of Faraday's in 1850, who shewed, 'that when two pieces of ice, with moistened surfaces, were placed in contact, they became cemented together by the freezing of the film of water between them, while, when the ice was below 32° F., and therefore dry, no effect of this kind could be produced. The freezing was also found to take place under water.' By a further series of experiments, Tyndall found that ice at 32° F. could be compressed into any form, and that no matter how great the bruising of its particles and the change of its shape, it would, from this property

of regelation, re-establish its continuous solid condition, if the particles of ice operated on were kept in close contact. These facts he applied to the motion of glaciers, asserting that the pressure of the parts of a glacier on each other, in a downward direction, produced by gravitation, was more powerful than the attraction which held the particles of the ice together—that, consequently, the ice was ruptured, to permit the motion of the glacier, the particles being, however, speedily reunited by regelation. The supposed viscous condition of ice he believed to be refuted by the fact that, whenever the glacier is subjected to tension, as in passing over a cascade, it does not yield by stretching, but always by breaking, so as to form crevasses. This theory, equally with that of Forbes, explains the known phenomena of glaciers, while the advantage is claimed for it of not drawing upon our imagination as to a required condition of the ice, but, by experiment, exhibiting ice from known causes producing effects on the small scale similar to those produced in nature on the large. Forbes, however, maintains (*Occasional Papers, &c.*, 1859) that all that is peculiar to Tyndall's theory was included in his own; and that the facts discovered and expounded by Faraday in 1850 had already been used by him as part of his theory in 1846. He says that his viscous theory included the notion 'of an infinity of minute rents; that it also embraces the substitution of the finite sliding of the internally bruised surfaces over one another;' and that it includes 'the reconsolidation of the bruised glacial substance into a coherent whole by pressure acting upon ice, softened by imminent thaw.'

Professor Tyndall re-introduces and re-asserts the gravitation theory of De Saussure as in part the cause of the glacier's motion; but the phenomena which he considers produced by a sliding motion of the whole mass over its bed—viz., the polishing and grooving of the rock below—can be produced by a substance whose motion is the result of a yielding of its parts, if that substance has sufficient consistence to retain firmly imbedded in its lower surface portions of rock to act as polishers, and it cannot be doubted that the ice of glaciers has such a consistency.

Some of the more remarkable phenomena of glaciers remain to be noticed. The surface of the glacier does not long retain the purity of the snow from which it is derived, but is speedily loaded with long ridges of debris called *moraines*. The mountains which rise on either side of the valley occupied by the glacier are continually suffering loss from the action of the rain, disruption by frost, and the impulse of avalanches. The materials thus liberated find their way to the glacier, and form a line of rock and rubbish on its two borders, of greater or less size, dependent on the friability or compactness of the adjacent mountains. The *lateral moraines* often reach to a great height, as much as forty or fifty feet above the level of the glacier. The whole ridge appears to consist of debris, but it is really a ridge of ice with a covering of foreign materials, which, by protecting the underlying ice from the heat which they radiate and only partially transmit, leave the moraine as a more and more elevated ridge, while the surface of the glacier is speedily melting. *Glacier tables* have a similar origin. A large and isolated mass of rock, resting on the glacier, protects the ice below; and as the glacier melts, it leaves the rock poised on the summit of an icy column. As the rays of the sun play on the table all day obliquely, the column is gradually melted from under the rock, until it slips off, and begins to form another table; while the unprotected column speedily melts and disappears.

Where two glaciers unite, the trails of rock on the inner margins unite also, and form a single ridge, which runs along the middle of the large trunk glacier, and is called a *medial moraine*. It is evident that the number of the medial moraines must thus depend upon the number of the branch glaciers, and must indeed be invariably one less. The glacier terminates amidst a mass of stones and debris, which having been carried down on its surface, are finally deposited by its melting at its extremity, forming there a *terminal moraine*. Sometimes a glacier decreases in size, either withdrawing from the valley, and leaving the terminal moraine as a barren waste of rocks, or melting on its superficies throughout its length, and depositing its lateral moraines as a ridge of debris on either side at some height above it on the mountain. The existence of such collections of rocks is plain evidence of the former position and altitude of glaciers, and even of their former occurrence in countries where they are now unknown.

It has been stated, that when the glacier is subjected to tension, the continuity of its parts is destroyed, and fissures, called *crevasses*, are formed. In passing over a brow on the channel, the ice invariably yields; at first, a deep crack is formed, which gradually widens until a fissure or chasm is produced across the glacier. Transverse crevasses disappear when the glacier reaches a level portion of its bed; the pressure bringing the walls again together, the chasm is closed up. Longitudinal crevasses are produced when the glacier escapes from a confined channel, and spreads itself over a wider area. The spreading of the margins causes a tension in the body of the glacier, which yields, and longitudinal fissures are formed. These occasionally rend the terminal front of a glacier. The smaller marginal crevasses are formed from the tension of the ice, produced by the normal motion of the glacier being retarded by the friction against the sides of its channel. The motion of the glacier is gradually accelerated from the margin inwards, consequently the lines of greatest tension are inclined downwards and towards the centre, more or less, in proportion to the rapidity of the motion. The crevasses formed by the yielding of the ice are at right angles to the lines of tension, and consequently point up the glacier.

The *veined structure* is apparently the result of pressure. The veins consist of blue ice penetrating the white mass of the glacier, and occur either in irregular directions, or producing a regularly laminated structure. The blue veins are portions of ice from which the air-bubbles have been expelled, and which are consequently more compact than the general substance of the glacier. The pressure is exerted in three directions, producing veins which are complementary to the three kinds of crevasses which have just been noticed. When the glacier passes over a level, or perhaps a gently rising channel, transverse veins are formed; when it is pressed through a narrower channel, longitudinal veins are produced; and the pressure at the margin produced by the retardation of the flow by friction causes the formation of marginal veins in the lines of greatest pressure, that is, at right angles to the marginal crevasses.

The melting of the ice on the surface of the glacier produces streams, whose course is often broken by crevasses, down which the water descends, finding egress at last through the cavernous mouth at the termination of the glacier, where it issues after being increased by other streams, which have by similar channels reached the bottom, as well as by the melting of the ice from the contact of the earth. The rushing water wears a shaft of greater

diameter than the crevasse, and this shaft often remains after the margins of the crevasse have been reunited. In the progress of the glacier, another crevasse intersects the bed of the stream, and down this the water is diverted, leaving the formed shaft or *moulin*, as it is called. The forsaken moulin has at its base a quantity of earth and stones collected by the stream from the surface of the glacier; these are gradually raised to the surface by the melting of the glacier, and eventually appear as cones of debris, sometimes rising high on columns of ice under the same influences as the glacier tables.

Glaciers are not necessarily peculiar to any country or zone, but wherever there are mountains of sufficient height, it may be expected that they may exist. In Europe, they are chiefly confined to the Alps and Norway. Having their origin in the region of perpetual snow, they reach far down into the valleys, the largest pushing themselves furthest down. That of Bossons at Chamouni, which comes from the highest part of Mont Blanc, reaches a point 5500 feet below the snow-line, where it is embosomed amongst luxuriant wood, and is almost in contact with cornfields. Hooker and others have described the glaciers of the Himalaya. Iceland and Spitzbergen also abound in glaciers. It is in such northern localities that the ends of the glaciers, resting on the waters of the ocean, get broken off by transverse crevasses, and float away as icebergs.

It has already been noticed that the former existence of glaciers is indicated by the occurrence of moraines. These have been noticed in various localities in Wales, England, and Scotland. They are referred to the period when the Boulder-Clay (q. v.) was deposited; and this, with the sands and gravels which are associated with it, are sometimes included under the title Glacial Deposits.

GLA'CIS (allied to glade in the sense of a lawn), in Fortification (q. v.), the slope of earth, usually turfed, which inclines from the covered-way towards the country. Its object is to bring assailants, as they approach, into a conspicuous line of fire from the parapet of the fortress, and also to mask the general works of the place.

GLADIATOR, in Antiquity, from *gladius*, a sword, was one who fought in the arena, at the amphitheatre at Rome, and in other cities, for the amusement of the public. The gladiators were generally slaves, bought and trained for the purpose, by masters who made this their business. The custom is supposed to have been borrowed from the East, and to have had its origin in the practice of human sacrifices, or that of taking the lives of captives or prisoners of war, in honour of heroes who had died in battle. Thus, in the *Iliad*, we read that Achilles sacrificed twelve Trojan prisoners to the manes of his friend Patroclus, and Virgil speaks of captives sent to Evander, to be sacrificed at the funeral of his son Pallas. The 'great custom' of the king of Dahomey thus finds warrant in classic antiquity; and the North American Indians, in putting their prisoners to death with tortures, have only refined upon an ancient barbarism.

After a time, all considerable funerals were solemnised by human sacrifices, which took the form of combats, in which, to increase the interest of the spectators, the prisoners were required to sacrifice each other; and as prisoners, and afterwards other slaves, were kept for this purpose, they were trained to fight with skill and courage, to make the spectacle more impressive. These contests first took place at funerals, but afterwards in the amphitheatre; and in process of time, instead of a funeral

rite, became a common amusement. The first we read of in Roman history was the show of a contest of three pairs of gladiators, given by Marcus and Decius Brutus, on the death of their father, in the year of Rome 490. In the year 537, a show of twenty-two pairs was given in the Forum. In 547, the first Africanus diverted his army at New Carthage with a gladiatorial exhibition. The fashion now rapidly increased. Magistrates, public officers, candidates for the popular suffrages, gave shows to the people, which consisted chiefly of these bloody and generally mortal encounters. The emperors exceeded all others in the extent and magnificence of these cruel spectacles. Julius Caesar gave a show of 320 couples; Titus gave a show of gladiators, wild-beasts, and sea-fights, for 100 days; Trajan gave a show of 123 days, in which 2000 men fought with and killed each other, or fought with wild-beasts for the amusement of the 70,000 Romans, patricians and plebeians, the highest ladies and the lowest rabble, assembled in the Colosseum. A vast number of slaves from all parts of the world were kept in Rome, and trained for these exhibitions. There were so many at the time of Catiline's conspiracy, that they were thought dangerous to the public safety, and it was proposed to distribute them among the distant garrisons.

Efforts were made to limit the number of gladiators, and diminish the frequency of these shows. Cicero proposed a law, that no man should give one for two years before becoming a candidate for office. The Emperor Augustus forbade more than two shows in a year, or that one should be given by a man worth less than half a million sesterces; but it was difficult to restrain what had become a passion, and men even had such contests for the amusement of their guests at ordinary feasts.

These shows were announced by show-bills and pictures, like the plays of our theatres. The gladiators were trained and sworn to fight to the death. If they shewed cowardice, they were killed with tortures. They fought at first with wooden swords, and then with steel. When one of the combatants was disarmed, or upon the ground, the victor looked to the emperor, if present, or to the people, for the signal of death; if they raised their thumbs, his life was spared; if they turned them down, he executed the fatal mandate. A gladiator who had conquered was rewarded with a branch of palm, and sometimes with his freedom. Though the gladiators at first were slaves, freemen afterwards entered the profession, and even knights. Senators and knights fought in the shows of Nero, and women in those of Domitian. The Emperor Constantine prohibited the contests of gladiators, 325 A.D.; but they could not at once be abolished. In the reign of Honorius, Telemachus went into the arena to stop the fight, when the people stoned him. They were finally abolished by Theodoric, 500 A.D.

GLADIOLUS, a genus of plants of the natural order *Iridaceæ*, with a tubular perianth, the limb of which is divided into six unequal segments, thread-like, undivided stigmas, and winged seeds. The roots are bulbous; the leaves linear or sword-shaped, whence the name (Lat. a little sword). The Cape of Good Hope produces the greater number of the known species, as well as of several allied genera once included in this. A few, however, are natives of other countries, and two or three are found in Europe. None are British. Most of the species have flowers of great beauty; and some of them are among the finest ornaments of our flower-borders and green-houses. They are propagated either by seed or by offset bulbs; and in the former way many fine new varieties have been produced. Extraordinary medicinal virtues were formerly ascribed

to the bulb of *G. commutata*, one of the European species, found as far north as Frankfort-on-the-

Gladiolus Ramosus.

Oder. The Hottentots eat the bulbs of some of the species, which contain a considerable quantity of starch.

GLADSTONE, THE RIGHT HON. WILLIAM EWART, statesman and orator, the third son of Sir John Gladstone, Bart., of Fasque, in Kincardineshire, was born, 1809, at Liverpool, where his father, originally of Leith, had won eminence and wealth as a West India merchant. Mr Canning was a frequent guest at his father's house when he visited his Liverpool constituents, and from the conversation of the great statesman, G. received impressions which gave a colour to his subsequent aims. He was sent to Eton, where he distinguished himself as a student, and afterwards entered himself of Christ Church, Oxford, where he closed a brilliant college career by taking a double first-class degree in 1831. He entered the House of Commons in 1832 for the Duke of Newcastle's borough of Newark. He held the post of Lord of the Treasury, and afterwards that of Under-Secretary of State for the Colonies in the Peel government, for a few months in 1834-1835. In 1838, he published his first work, *The State in its Relations with the Church*, which gave occasion to Mr Macaulay to describe him, in a celebrated review of his work, as a 'young man of unblemished character, the rising hope of those stern and unbending Tories' who followed Sir Robert Peel, while they abhorred his cautious temper and moderate opinions. In 1841, G. became Vice-President of the Board of Trade in the Peel administration, and in 1843, President of the Board. Next to his chief, he took the most prominent part in the revision of the tariff and reduction of import duties, which reached their natural development in the repeal of the Corn Laws. He resigned office in February 1845, when Sir R. Peel proposed to increase the endowments of the College of Maynooth, a proposal at variance with all the principles laid down by G. in his work. He rejoined the ministry in December 1845, succeeding the Earl of Derby (who refused to be a party to the repeal of the Corn Laws) as Colonial Secretary. He rendered Sir R. Peel eloquent and effective aid in carrying the great measure of free trade through the House of Commons, but paid the penalty in the loss both of his office and his seat, for the then Duke of Newcastle, claiming to 'do what he liked

with his own,' refused to sanction his re-election for Newark. In 1847, he was elected M.P. for the university of Oxford, which he has ever since continued to represent. During a visit to Naples in 1850, he was induced by curiosity to attend the trial of M. Poerio, who was sentenced to several years' imprisonment, and subjected to indignities and cruelties which roused the generous indignation of the English statesman. The dungeons of the kingdom of the Two Sicilies at this period swarmed with political prisoners, and G., in a letter to the Earl of Aberdeen, made all Europe ring with the story of their sufferings and their wrongs. He has since advocated the cause of Italian independence in many eloquent speeches. In 1851, he opposed the Ecclesiastical Titles Bill, brought in by Lord J. Russell, thinking that no legislation was necessary, and that the act savoured of religious persecution. After refusing an offer to hold office under Lord Derby, he became Chancellor of the Exchequer in the coalition government formed by the Earl of Aberdeen in 1852. When that government fell before a motion in the House of Commons for inquiring into the state of the army before Sebastopol, G. continued for a brief period a member of the cabinet of Lord Palmerston, but soon retired, from an unwillingness to consent to the appointment of the Sebastopol committee. G. then went into opposition, and in 1857 made an eloquent and damaging speech on Mr Cobden's motion condemnatory of Sir John Bowring's proceedings in China, which brought about the defeat of Lord Palmerston, and the dissolution of parliament. In 1858, G. again refused to take office under Lord Derby, but consented to visit the Ionian Islands as Lord High Commissioner Extraordinary. In the second Palmerston administration, he resumed the post of Chancellor of the Exchequer. In 1860, he carried through parliament the commercial treaty with France, which has largely increased the trade between the two countries. His financial scheme, involving the repeal of duties on many articles of general consumption, the simplification of the tariff, an increase in the income tax, and the abolition of the paper duty, was strongly but unsuccessfully opposed in the House of Commons. In the Upper House, the paper duty repeal bill was thrown out on financial grounds. G. boldly denounced this interference with the taxing privileges of the Commons as 'the most gigantic and the most dangerous innovation that has been attempted in our times.' In 1861, he incorporated the repeal of the paper duty in the financial scheme of the year, and had the satisfaction of witnessing the removal of the last obstacle to the dissemination of knowledge. As an orator, G. has no superior among his contemporaries, while as a master of debate he stands unrivalled. His copiousness and wealth of diction are wonderful. He possesses a voice of great power and compass, an earnest and persuasive intonation, a perfect elocution, and easy and expressive gestures. Best of all, his eloquence is animated by principle and conscience, as well as high intellect. G.'s political opinions are probably not yet fully developed, but it may be hoped that a magnificent career of public usefulness still lies before him. In 1858, he published a work on *Homer and the Homeric Age*, the leading idea of which is the strictly historical aim and character of the Homeric poems. He assumes the personality of Homer, and the unity of authorship in the two great poems, and he reads in Homer the history, politics, ethics, and theology of the Homeric age. G. was elected Rector of the university of Edinburgh in 1859. He is still (1863) Chancellor of the Exchequer in the administration of Lord Palmerston.

GLAGOL, GLAGOLITZA, GLAGOLITES, an ancient Slavonic alphabet, principally used in several Roman Catholic dioceses of Istria and Dalmatia, in the psalms, liturgies, and offices of the church. Among these Illyrian adherents to the communion of Rome, mass is not celebrated in Latin, but in an ancient Slavonic dialect, written in this peculiar alphabet, the invention of which is popularly attributed to St Jerome. The use of this liturgy was confirmed to the priesthood by a bull of Pope Innocent IV., 1248. Of the antiquity of this alphabet, the savants have maintained a great variety of opinions. Dobrowsky laid the foundation of a critical investigation of the subject, and has been followed by Kopitar, Jacob Grimm, Ivan Preis, &c. A Glagolitic MS. of the 11th c., belonging to Count Klotz, published under the title of *Glagolita Clozianus* (Vienna, 1836), proves a higher antiquity than some had been willing to allow. Grimm supposes the Glagol alphabet very ancient, from its Runic character; but Preis thinks it more modern than the Kyrillick. The name Glagol is supposed by Kopitar to have been taken from the word *glogolati*, which frequently occurs in the liturgies, and which, though unknown to the Servo-Croatians, signifies in the ecclesiastical idiom, *to speak*. Glagol means *word* or *speech*.

GLAMORGANSHIRE, the most southerly of the counties of Wales, is bounded on the S. and S.W. by the Bristol Channel, on the W. by the county of Caermarthen, on the N. by Brecknock, and on the E. by Monmouth. Area, 547,494 acres; pop. (1851) 231,849; (1861) 317,751. The coastline, following the principal windings, is about 90 miles in length, and its irregularities occur chiefly in the western portion of the county, and are formed by Swansea Bay and the peninsula of Gower (q. v.). The whole of the northern district is covered with mountains, the highest of which, however, Llan-gainor, is only 1859 feet in height. This district comprises the richest coal-bed in the kingdom. The southern portion of the county, called the 'Vale of Glamorgan,' forms a great level, and is by far the most fertile part of South Wales. Its soil is a reddish clay, resting on limestone, and is excellently adapted for the growth of wheat, which is here raised in rich and heavy crops. The mountainous district is intersected by numerous and deep valleys, affording good pasturage for sheep and cattle, and is the source of many of the streams of the county. The chief rivers are the Runney, the Taff, the Neath, and the Tawe; all of them running southward from the mountains into the Bristol Channel. Besides coal, anthracite or stone-coal and coking-coal, with iron-stone and lead, are found in greater or less quantity. The ironworks at Merthyr-Tydvil are probably the most extensive in the world, and there are many others of scarcely less importance throughout the county. At Neath and Swansea are large copper smelting-works, to which ore is brought from South America, and even from Australia. Lead and tin ores are also brought from considerable distances to this county to be smelted. Wheat, barley, oats, and potatoes are the chief crops raised; and butter and cheese are largely produced and exported. The county of G. returns two members to the House of Commons.

Originally included in the territory of the Silures, and afterwards (under the Romans) in that of Britannia Secunda, and possessing some interesting Roman remains, the district of G., about the close of the 11th c., fell into the hands of the Anglo-Norman barons, and subsequently became, through marriage, a possession of the Duke of Gloucester, afterwards Richard III. The county contains many memorials of the middle ages, in its ruined

castles and religious houses. Of these, Oystermouth Castle, a bold and noble ruin overlooking Swansea Bay, Caerphilly Castle, and Margam Abbey may be taken as perhaps the finest remaining specimens.

GLANCE (Ger. *Glans*), a term often applied is popular language, and also by mineralogists, to a numerous order or family of minerals, of which *Galena* (q. v.) or *Lead-G.* may be regarded as a type. All of them are metallic, and many of them are known by names indicating the metal which is their principal constituent, as *Lead-G.*, *Silver-G.*, *Bismuth-G.*, &c. In these and many other species, the metal is combined with sulphur, so that the mineral is a sulphuret, but there are also numerous species of G. in which sulphur is not present, but selenium, arsenic, or tellurium takes its place. In some kinds also, two or more metals are present instead of one, in combination with one or other of these non-metallic or semi-metallic substances. Thus, *Gold-G.*, or *Silvanite*, consists of gold and silver in combination with tellurium: it occurs in veins in porphyry, in Transylvania, and is wrought for the sake of both the precious metals which it contains. Several kinds of G. are very valuable ores, as *Lead-G.* or *Galena*, *Copper-G.* or *Redruthite*, and *Silver-G.* or *Argentite*. Although mineralogists have adopted the names *Pyrites*, *Glance*, and *Blende* as names of orders or families, the limits and distinctions of these groups are not well marked. All kinds of G. are fused without much difficulty by the blowpipe. They are also soluble in acids.

GLANCE-COAL. See **ANTHRACITE** and **COAL**.

GLANDERS is a malignant disease of the equine species, characterised by the appearance within the nostrils of little holes or ulcers, remarkable for their rugged, inflamed, undermined edges, their discharge of sticky, greenish, unhealthy pus, their tendency to spread, and their resistance of treatment. The blood of glanderous subjects is deficient in red globules, contains an excess of albumen and fibrine, and in this vitiated and deteriorated state is inadequate properly to nourish the body, which consequently becomes weak and wasted. The mucous membranes are also irritable and badly nourished; there is consequently impaired respiration, an obstinate choking cough, and relaxed bowels. The lymphatic glands and vessels become inflamed, and in their swollen state may be distinctly felt about the throat and underneath the jaws, and also in the limbs, where they frequently run on to ulceration, constituting *Farcy* (q. v.). Glanders is produced by any cause which interferes with the purity or integrity of the horse's blood, or produces a deteriorated or depraved state of his system. It has been frequently developed in healthy animals by their breathing for a short time a close, impure atmosphere, and cases of this sort were thus produced amongst the horses of several of our cavalry regiments, whilst being transported in badly constructed, overcrowded vessels to the Crimea in 1854. Confined, overcrowded, badly ventilated stables are almost equally injurious, for they prevent the perfect aeration of the blood, and the prompt removal of its organic impurities. Bad feeding, hard work, and such reducing diseases as diabetes and influenza, also rank amongst the causes of glanders. A small portion of the nasal discharge from a glandered horse coming in contact with the abraded skin of man, communicates the loathsome and fatal disease, from which so many attendants of horses have died, and government by the act Vict. 16 and 17, of date 14th August 1853, very properly compels the immediate destruction of every glandered horse. Whilst oxen and dogs are exempt from it, donkeys suffer

generally in the acute form, often dying in eight or ten days. Horses frequently have it in a chronic form, and if well fed and managed, sometimes live and work for years. In the old coaching-days, some stages were known to be worked by a glandered team, but no animal with glanderous ulcers or discharge should on any account be preserved, for, besides being perfectly incurable, the fatal disease is communicable not only to healthy horses, but also to human beings.

GLANDS are divided by anatomists into two great classes, viz., true secreting glands and ductless glands.

The first class constitute special organs which are destined for the production of the chief secretions; as, for example, the lachrymal, mammary, and salivary glands, the liver, pancreas, kidneys, &c.; while the suprarenal capsules, the spleen, the thymus, and the thyroid belong to the second class.

An ordinary secreting gland consists of an aggregation of follicles, all of which open into a common duct, by which the glandular product is discharged. The follicles contain in their interior Cells (q. v.), which are the active agents in the secreting process; while their exterior is surrounded by a net-work of capillaries, from whose contents the materials of secretion are extracted.

Fig. 1.—Lobule of Parotid Gland of an Infant:
Filled with mercury, and magnified 20 diameters.

The simplest form of a gland is the inversion of the surface of a secreting membrane into follicles, which discharge their contents upon it by separate mouths. Of this we have examples in the gastric glands and follicles of Lieberkühn described and figured in the article DIGESTION. Dr Carpenter very well exhibits the commencement of the progressive complication which is observed in most of the glandular structures occurring in man and the higher animals in the accompanying diagram (fig. 2), where A represents a

Fig. 2.

portion of the proventriculus of a falcon, in which follicles formed by simple inversion occur, while B represents a gastric gland from the middle of the human stomach, and C a still more complicated form, produced by the follicles doubling upon themselves, taken from near the pylorus.

The articulates (for example, insects) present glandular structures which can be unravelled much easier than the glands of vertebrate animals; and the forms, in all of which a large amount of secreting surface is presented in comparatively little space, are often very graceful. In the accompanying group (fig. 3), the first two represent different forms of salivary glands, the third is a reproductive gland,

while the fourth and fifth are glands yielding the acid matter which some insects secrete.

Fig. 3.

1, part of the salivary gland of *Nepa Cincta* (after Ranzoh); 2, salivary vessel of *Cicada Orni* (after Sucoow); 3, testes of *Staphylinus Maxillaris*; 4, secreting gland of *Chlamys Velutinus*; 5, secreting gland of *Calathus Fulvipes*.

To understand the structure of a complex gland like the liver or kidney, it must be followed from the simplest form in which it is known to occur through its various degrees of complication. In this way the liver may be traced, from the lowest mollusca (where it exists as simple follicles, lodged in the walls of the stomach, and pouring their product into its cavity by separate orifices) up to man, in whom it is an organ of extreme intricacy; and similarly in the early foetal state of the higher animals, the liver and other secreting organs more or less resemble

Fig. 4.—Mammary Gland of *Ornithorhynchus*.

the persistent state of those parts in animals lower in the animal scale. In the same way, the Mammary Gland (q. v.), which is a structure of considerable complexity in the higher mammals, presents a very simple arrangement in the lowest type of this class, the *ornithorhynchus*, being merely a cluster of caecal follicles, each of which discharges its contents by its own orifice.

Sometimes a gland has several ducts (as, for example, the lachrymal gland), but, as a general rule, the most important glands have only a single canal, formed by the union of the individual ducts, which conveys away the product of the secreting action of the whole mass.

Whatever be the complexity in the general arrangement of the elements of a gland in the higher animals, these elements are always found to resolve themselves into *follicles* or *tubuli*, which enclose the true secreting cells.

The second class of glands resemble the secreting glands in external conformation, and in the possession of a solid parenchymatous tissue, but differ from them in the absence of a duct or opening for the removal of the products of secretion; and indeed,

except in the case of the thymus, no material resembling a secreted product is yielded by any of them. In all of them, the tissue mainly consists of cells and nuclei, with a great abundance of blood-vessels. They may probably be regarded as appendages to the vascular system; and from the absence of any excretory duct, they have received the name of *vascular ductless glands*.

The *Lymphatic Glands* belong to a different class of structures, and will be described in the article on the LYMPHATIC SYSTEM.

GLANDS, DISEASES OF. The lymphatic glands are subject to enlargement from acute inflammation and abscess, usually in consequence of irritation of the part from which their lymphatics spring, as in the case of scarlet fever, in which the glands of the throat are affected; in gonorrhoea, the glands of the groin, &c. The treatment of such abscesses belongs to the ordinary principles of surgery. See ABSCESS. A much more troublesome affection of the glands is the slow, comparatively painless, at first dense solid swelling which they undergo in Scrofula (q. v.), which tends very slowly, if at all, to suppuration, and sometimes remains for years. In Syphilis (q. v.) and Cancer (q. v.), there are also enlargements of the lymphatic glands. Scrofulous or tubercular disease of the mesenteric glands in children constitutes *Tabes mesenterica* (q. v.). The larger glands, as the Liver, Kidney, Pancreas, Spleen, Thyroid, Thymus, Testicle, and even the Pituitary Gland, have all their special diseases, which will be noticed, so far as necessary, in treating of these organs.

GLANVILLE. The earliest treatise on the laws of England, *Tractatus de Legibus et Consuetudinibus Angliæ*, is written by Glanville. Of this work, Professor Robertson says (*Hist. of Charles V.*), that it is supposed to have been the first undertaking of the kind in any country in Europe. It was composed about 1181. The author is generally supposed to have been Ranulphus de G., chief-justice in the reign of Henry II. Sir Matthew Hale, while he admits the date of the work to have been in the reign of that monarch, appears to hesitate to ascribe the authorship to the chief-justice. Lord Campbell (*Lives of the Chief-Justices*, i. 25) remarks that G., in some points, is still of authority, 'and may be perused with advantage by all who take an interest in our legal antiquities. This author is to be considered the father of English jurisprudence. Bracton, who writes in the following century, is more methodical, but he draws largely from the Roman civil law, and is often rather speculative; while Glanville actually details to us the practice of the *Aula Regis* in which he presided, furnishes us with a copious supply of precedents of writs and other procedure then in use, and explains with much precision the distinction and subtleties of the system which, in the fifth Norman reign, had nearly superseded the simple juridical institutions of our Anglo-Saxon ancestors.' This work was first printed in the year 1554, at the instance of Sir W. Stanford, a judge of the Common Pleas. The treatise of G. closely resembles the Scottish *Regiam Majestatem* (q. v.). 'The latter,' says Coke (*Inst. iv.* 345), 'doth in substance agree with our Glanville, and most commonly *de verbo in verbum*, and many times our Glanville is cited therein by special name.' A dispute has arisen, in consequence of this close similarity, as to which country shall claim the honour of producing the original work. Mr Erskine does not hesitate to claim the distinction for Scotland; but Lord Stair, following the opinion of Craig, frankly admits 'that those books, called *Regiam Majestatem*, are no part of our law, but were compiled for the customs of England, in thirteen books,

by the Earl of Chester, and by some unknown and inconsiderate hand stolen thence, and rearginate in those four books which pass amongst us' (Stair, i. 1, s. 16).

GLARUS, a canton in the north-east of Switzerland, is triangular in shape, and is bounded on the N.-E. by the canton of St Gall, on the S.-E. by that of the Grisons, and on the W. by those of Schwytz and Uri. It has an area of 262 square miles, and in 1860, it had 33,459 inhabitants, of whom 5866 were Catholics, the others almost all Calvinists. The surface is mountainous, the highest peak being that of Tödi or Dödi, which reaches a height of 11,890 feet. From the foot of this mountain, the Linth, the chief river, flows north-north-east, through the middle of the canton, and empties itself into the Lake of Wallenstadt. The principal valleys, after that of the Linth, are the Sernthal and the Klönthal, both formed by tributaries of the Linth. The climate is very severe, and only one-fifth of the land is arable. This canton, in which the rearing of cattle was formerly the main pursuit of the inhabitants, is now an important manufacturing district. The principal manufactures are cotton, woollen, muslin, and silk goods, and paper and slates. Great part of the manufactures are exported to the East, to North Africa, America, and China. The green cheese called *Schabziger*, which is wholly made here, and other agricultural products, are exported. In none of the Swiss cantons does the population so slowly increase as in that of Glarus. The old homely manners, and many even of the customs of antiquity, still prevail among the people. In the earliest times, G. was reckoned sometimes as a part of Rhetia, sometimes as a part of Swabia, and was peopled by German settlers. After various changes, it passed into the possession of the Dukes of Austria, but ultimately secured its independence by the victories of Näfels in 1352 and 1388, when it joined the Swiss confederation. The chief town is Glarus, with a large Gothic church, which serves both for Catholics and Protestants and in which Zwingli was parson from 1506 to 1516. Pop. 4082.

GLASGOW, the industrial metropolis of Scotland, is, after London, one of the largest and most important cities in the kingdom. It is situated on the Clyde, in the lower ward of Lanarkshire, and occupies chiefly the north side of the river, but has large and populous suburbs on the south side. The river is crossed by three stone bridges, two of which are of granite, measuring 60 feet in breadth over the parapets, and much admired for their light and graceful architecture, and by two suspension-bridges for foot-passengers, each of a single span. Below the bridges, there are ferry-boats plying at all hours.

The ground upon which G. is built is, for the most part, level, but in the north and north-west districts, there are considerable elevations. Owing to the number of cotton-factories, chemical works, foundries, and work-shops of all kinds, the city has a somewhat dingy and smoky aspect; while many of the streets are continually thronged with passengers, and noisy with carts, cabs, and omnibuses. In other respects, it has many attractions. The houses facing the river stand well back, leaving spacious thoroughfares on each side, and affording full and noble views of the bridges, of several handsome street ranges and public buildings, and of the harbour with its steaming funnels and forests of masts. Most of the leading streets run from east to west, parallel with the river, and almost all the streets, except in the oldest parts of the city, are laid off in straight lines. The houses are generally lofty, and built of freestone, the floors of each

tenement being usually occupied by separate families, entering by a common stair. In the fashionable quarters, what are called 'self-contained' houses prevail. G. has comparatively few squares or other open spaces; but it has three public parks—two of them of great extent, and the third of great beauty—namely, the Green (140 acres), occupying the level next the Clyde at the east end; Queen's Park (upwards of 100 acres), finely situated on a rising-ground to the south; and Kelvingrove (40 acres), rounding the face of a hill crowned with noble terraces, and sloping down to the Kelvin, at the west end. The city is about three miles in length from east to west, and is about eight miles in circumference.

G. had its first nucleus in the cathedral, and afterwards in the university, both in the north-east part of the city—the former on a height on the banks of the Molendinar stream, which runs between the old burying-ground and a steep rocky eminence formerly known as the Fir Park, but now transformed into the Necropolis, a modern cemetery, studded and crowned with monuments. It is from this ravine that the name G. is supposed to have been derived, etymologists professing to find in it two Celtic words signifying a 'Dark Glen.' St Kentigern, or St Mungo, founded a bishopric on the banks of the Molendinar about 560; but for more than five hundred years afterwards, the history of the place is a blank. About the year 1115, David, prince of Cumbria (afterwards king of Scotland), restored the see, and appointed his preceptor, John, to the bishopric, who laid the foundations of a cathedral, which was replaced by the present pile, founded by Bishop Jocelin in 1181. In 1190, King William the Lion erected G. into a burgh, with the privilege of an annual fair; but for a century and a half later, it continued an insignificant town of not more than 1500 inhabitants. In 1345, Bishop Rae built the first stone bridge across the Clyde; and in 1451, Bishop Turnbull established the university, having obtained a bull for that purpose from Pope Nicholas V. The latter event gave a considerable impetus to the place; yet, in 1556, G. only ranked eleventh in importance among the towns of Scotland.

The city as it now exists is almost wholly modern, having quintupled in dimensions during the last 60 years. This immense growth has arisen from its situation in the midst of a district abounding in coal and iron, and from the facilities afforded by the Clyde for the cultivation of a world-wide commerce. At the same time, it must be admitted that much of its prosperity is due to local ingenuity and enterprise. It was here that James Watt, in 1765, made his memorable improvement on the steam-engine; it was here that Henry Bell, in 1812, first (in the old world) demonstrated the practicability of steam-navigation. On the widening and deepening of the river, so as to render it navigable by vessels of 2000 tons burden, an enormous sum has been expended. The harbour of Port-Dundas, on the Forth and Clyde Canal, situated on the high ground north of the city, has likewise afforded facilities to its commerce. The enterprising spirit of the inhabitants began to manifest itself during the 17th century. Sugar-refining, the distillation of spirits from molasses, and the manufacture of soap, were among their earlier industries. The opening up of the American colonies to Scotch enterprise after the Union gave an immense increase to its commerce. G. became the chief emporium of the tobacco trade, and its Virginian merchants formed a local aristocracy, remarkable for wealth and *hauteur*. This trade was at length paralysed by the American war; but sugar cultivation in the West Indies,

and the introduction of the cotton manufacture, opened up new paths to opulence. Calico-printing, turkey-red dyeing, beer-brewing, and other branches followed; and with the rapid expansion of the iron trade, including machine-making and steam-boat building, the city has attained its present magnitude. Among its thousand chimney-stalks, there is one of 460 and one of 450 feet, being the highest in the British dominions. The latter carries aloft the noxious vapours of St Rollox, the largest chemical works in the world, covering 12 acres of ground, and employing upwards of 1000 men.

In all that relates to lighting, paving, sewerage, and the like, G. deserves laudatory mention. The city is governed by a lord provost, 8 bailies, and 39 councillors, to whom are added the dean of guild from the Merchants', and the deacon-convenor from the Trades' House. The sheriff and four sheriff-substitutes exercise within the city a co-ordinate jurisdiction with the magistrates, and preside over various civil and criminal courts. Much of the spirit which characterises the manufacturing and commercial affairs of G. has been carried into its municipal arrangements. Corporation halls, comprising a valuable gallery of paintings, have been secured for the citizens; public parks have been purchased at great cost, and laid out in a style of unsurpassed beauty; and a supply of water has been introduced from Loch Katrine at the bountiful rate of 21,000,000 gallons a day. G. has 20,260 registered voters, and sends two members to parliament.

Many of the public buildings deserve notice. The cathedral, which has lately been restored, and the windows enriched with stained glass, chiefly from Munich, is one of the finest First Pointed churches in the kingdom. The Royal Exchange, in Queen Street, several of the banks, and many of the churches, likewise present fine specimens of architecture in a variety of styles. G. has three equestrian statues, one of William III. at the Cross, another of the Duke of Wellington in front of the Royal Exchange, and the third of Queen Victoria in St Vincent Place. The last two are by Marochetti. In the Green there is an obelisk, 144 feet high, to Nelson, forming a conspicuous object in the landscape. This tall structure, which stands quite alone, has been twice struck by lightning, once in 1810, and again in 1861. In George's Square there are a column surmounted by a statue of Sir Walter Scott; a fine statue of Sir John Moore, by Flaxman; a statue of James Watt, in a sitting posture, by Chantrey; and a statue of Sir Robert Peel, by John Mossman. A marble statue of Pitt, by Flaxman, has lately been removed from the old town-hall at the Cross to the new Corporation Galleries, Sauchiehall Street. Charitable institutions and benevolent societies abound; and zealous and successful efforts have lately been made to provide cheap and innocent amusements for the working-classes. There are two theatres, two museums, and numerous halls in which soirées and concerts are held almost nightly during winter. The wealthier inhabitants migrate to the coast in shoals during the summer, and cheap Saturday excursions by river and rail are extensively taken advantage of by the working-classes. To the north-west of the city is a botanic garden of about 40 acres, which is thrown open every summer, during the fair holidays, at a merely nominal charge. In the fair week of July 1861, the number of visitors to the garden amounted to 17,344. Besides the Necropolis, there are several other garden cemeteries in the vicinity, of which Sight-hill, occupying a northern elevation, is the most picturesque.

G. has three daily, and upwards of a dozen weekly newspapers. It has 175 churches and chapels, viz.: Established Church, 40; Free Church, 43; United Presbyterian, 37; Roman Catholic, 12; Independent, 9; Baptist, 7; Episcopalian, 5; Reformed Presbyterian, 4; other bodies, 18. In 1801, the population was 83,769; in 1861, it amounted to 446,639; and it is now estimated at nearly half a million.

GLASGOW, THE UNIVERSITY OF, was founded in 1451 by Bishop Turnbull, who procured a bull of ratification from Pope Nicholas V. In 1460, James first Lord Hamilton, endowed a college on the site of the present buildings, the older portions of which were erected between 1632 and 1656. During the stormy times of the Reformation, the university was well-nigh destroyed. Queen Mary exerted herself to restore the tottering institution: she bestowed on it the manse and kirk of the Preaching Friars, with 13 acres of adjacent ground. In 1577, James VI. endowed it with the rectory and vicarage of the parish of Govan, and granted a new charter, which still continues in force. The professoriate, which was originally limited, gradually increased with the intellectual necessities of the times and the advancement of learning and science.

Chairs, Office-bearers, Degrees.—The office-bearers of the university consist of Chancellor, Rector, Principal, and Dean of Faculties. The Chancellor, holds his office for life, and up to the present time has been elected by the senate; but the next, and all future elections, will take place by the university council, as in Edinburgh University; the Rector is elected triennially by the matriculated students, who are divided, according to their place of birth, into four nations—*Glottiana* (Lanarkshire), *Transforthana* (Scotland north of the Forth), *Rothsiana* (Buteshire, Renfrewshire, and Ayrshire), *Londoniana* (all other places). The Dean of Faculties is elected annually by the senate. The duties of Chancellor and Rector are chiefly honorary. The chairs are Latin, Greek, Mathematics, Logic, Natural Philosophy, Moral Philosophy, English Language and Literature, Anatomy, Physiology, *Materia Medica*, Practice of Physic, Natural History, Chemistry, Clinical Surgery and Medicine, Midwifery, Botany, Surgery, Oriental Languages, Divinity, Church History, Biblical Criticism, Civil Law, Conveyancing, Civil Engineering, and Practical Astronomy. The degrees granted are Master of Arts, Doctor of Medicine, Master of Surgery, Bachelor of Divinity, Doctor of Divinity, Doctor of Laws, and Bachelor of Laws, the last three being honorary degrees. The ceremony of graduation was of old conducted with no little pomp through all its stages, from its beginning in what was called 'the Black Stone Examination,' to its close in the act of 'Laureation' in the College Hall, or one of the city churches. The number of matriculated students now averages about 1200; they reside outside the college walls; and those in attendance on classes in the Faculty of Arts wear scarlet gowns.

Bursaries and Exhibitions.—The *Senatus Academicus* has in its gift about 30 bursaries, and the funds attached to several of these are applicable to from four to six students: their yearly values range from £6 to £50, and some may be held for a period of four years. **The Oxford Exhibition.**—In 1677, John Snell, a native of Ayrshire, afterwards of Uffeton in Warwickshire, presented the university with an endowment, consisting of a landed estate, for the purpose of supporting at Balliol College, Oxford, ten students who had previously studied at Glasgow. The property was let in 1809 on a case of 21 years, at an annual rental of £1500,

and the ten exhibitors received £133, 6s. 8d. per annum each.

Libraries, Museums, &c.—The library was founded prior to the Reformation, and now contains about 105,000 volumes. It is supported from the interest of sums bequeathed by individuals, from graduation fees, and from contributions of students. Subsidiary libraries are attached to several of the classes, the books being selected with a view to the subjects treated of in each class. In July 1781, the celebrated Dr William Hunter of London framed a will, leaving to the principal and professors of the university his splendid collection of coins, medals, and anatomical preparations; and for the accommodation and conservation of these, a building was erected in 1804 within the college precincts at a cost of £12,000. The university also possesses an observatory and a botanical garden, and several of the professors have collections of apparatus attached to their classes, illustrative of the courses there delivered.

Eminent Professors and Students.—Among the men of eminence who have taught or studied in the university, are Bishop William Elphinstone, John Major, John Spottiswoode, Andrew Melville, James Melville, Robert Boyd of Trochrig, John Cameron, Zachary Boyd, Robert Baillie; James Dalrymple, first Viscount of Stair; Gilbert Burnet, bishop of Salisbury; Dr John Douglas, bishop of Salisbury; Dr Robert Simson, Francis Hutcheson, Dr William Hunter, Dr James Moor, Dr Adam Smith, Dr Thomas Reid, Dr William Cullen, Dr Joseph Black, Dr Matthew Baillie, Professor John Miller, Thomas Thomson, Francis Jeffrey, John Gibson Lockhart, Sir William Hamilton.

GLASS, from the *Fr. glace* (Lat. *glacies*), ice which it resembles in its transparency. Glass is essentially a combination of silica with some alkali or alkaline earth, such as lime, barytes, &c. Generally speaking, it is understood to be a silicate of soda, or a combination of silica or flint with one or more of the salts of sodium, with the addition, for some purposes, of certain metallic oxides and other substances.

History.—The invention of glass dates from the earliest antiquity, and the honour of its discovery has been contested by several nations. As the oldest known specimens are Egyptian, its invention may with great probability be attributed to that people. It is mentioned as early as the 5th or 6th dynasty, and called *bashnu*, the Coptic *bijni*; and articles made of it are represented in the tombs of the period; while its fabrication is depicted in sepulchres of the 12th dynasty—i. e., about 1800 B.C. The glass of Egypt was generally opaque, rarely transparent, and always coloured, the articles made of it being of small size, and principally for adornment, as beads, vases, small figures, and objects for inlaying into wood or other material. Specimens exist of this glass bearing the name of the queen Hatshepsut of the 18th dynasty, 1445 B.C., and vases of blue glass, with wavy lines in white, light-blue, yellow, black, red, and green, of that and a later age, have been discovered. The Egyptians also successfully imitated precious and other stones in glass—as emeralds, lapis lazuli, turquoise, jaspers, onyx, and obsidian; for this purpose, they used nearly the same materials as at present, employing manganese, copper, iron, cobalt, gold, and tin. Transparent glass, indeed, does not appear earlier in Egypt than the 26th dynasty, about 750 B.C., when bottles and a few other objects—as figures for inlaying, and beads imitating gems—were made of it. According to Herodotus, the Ethiopians, two centuries later, placed their mummies in glass

confirm; but the fact has never been proved by any as yet discovered.

Under the native Pharaohs, Egyptian glass seems to have been extensively exported to Greece and Italy, and its reputation still continued under the Ptolemies, when the furnaces of Alexandria produced glass vases of numberless shapes and considerable size. At this period, the Egyptians invented the *millefiori* glass, consisting of small threads of glass arranged vertically and then fused, so that the whole rod thus formed was of one pattern; and by cutting off slices, each piece reproduced the same pattern. The glass beads of *madrepore* glass, which are found in the tombs of Greece and Italy, and are formed by placing slices of such rods in a mould and fusing the whole, are probably of Egyptian or Phœnician origin. Egypt still retained the pre-eminence in the manufacture of glass under the Romans, the sand of Alexandria being indispensable for the finest qualities, and it exported glass to Rome. Hadrian, on his visit, was struck with the activity of the manufacture, and sent to his friend, the Consul Servianus, one of the vases, called *allosontes*, or 'opalescent;' and the Roman writers mention with admiration the melting, turning, and engraving of Egyptian glass. To the most flourishing period of the empire are to be referred certain vases and slabs with white camei figures of fine execution in relief on a blue background, and plates of opaque glass for inlaying the walls of rooms, such as those which are said to have decorated the mansion of the usurper Firmus. The art of glass-making, in fact, has never become extinct in Egypt, the Fatimite Califs having issued glass coins in the 10th and 11th centuries, and beautiful lamps of glass enamelled on the surface with various colours having been made in the 14th century. Although the art of glass-making has fallen to the lowest ebb in Egypt, the workmen are said to manifest considerable aptitude in its production.

After the Egyptians, the people of antiquity most renowned for glass were the Phœnicians, who were the legendary inventors. Certain of their merchants, it is said, returning in a ship laden with natron or soda, and having been compelled by stormy weather to land on a sandy tract under Mount Carmel, placed their cooking-pots on lumps of natron on the sand, which, fused by the heat of the fire, formed the first glass. Sidon, indeed, was long celebrated for her glass-wares made of the sand brought down from Mount Carmel to the mouth of the river Belus. The nature, however, of the earliest Phœnician glass is unknown, unless the opaque little vases of the toilet found in the tombs of Greece and Italy, and the beads of the same discovered in the barrows and tumuli of the old Celtic and Teutonic tribes, were imports of the Phœnicians. The vases of Sidon were, however, highly esteemed at Rome under the Antonines, fragments of bowls of blue and amber glass, with the names of the Sidonian glass-makers, Artas and Ireneus, stamped in Latin and Greek, having been found in the ruins. Perhaps the Assyrian glass vases were made at Sidon; at all events, the earliest dated specimen of transparent white glass is the vase having upon it stamped or engraved in Assyrian cuneiform a lion and the name of Sargon, who reigned 722 B.C., found at Nimrud by Mr Layard; and glass seems to have been imported or even made in Assyria as late as the time of the Parthians, when Nineveh became the Roman colony of Claudiopolis. Under the Sassanides, moulded glass vessels, elaborately decorated, were made, as is shewn by the cup of Chosroes, 531–579 A.D., in the Louvre; and Persia continued to manu-

facture glass vessels in the Middle Ages. The Arabs seem to have derived their glass from the Byzantines, and specimens introduced into Europe

Fig. 1.—Glass Vase, bearing the name of Sargon, from Nimrud.

by the Crusaders were called in royal and other inventories Damascus glass; this was coloured, and not plain. Although the art of glass-making appears to have been practised in remote times, this nation does not appear to have attained any proficiency in it, and is content at the present day to re-melt European glass; while some of its highest efforts do not exceed the imitation of jade, and other stones. There is still an extensive use of glass-beads in the East, which are chiefly made at Khalib or Hebron. Glass was equally unknown to the Hindus, except the production of a few trinkets and inferior objects, till the settlement of Europeans in India; and the country was, at the remotest period, supplied by Phœnician, and, in the Middle Ages, by the Venetian traders. Although Josephus claims the invention of the art for the Jews, no remains of Jewish glass are known, and it is probable that the Jews were principally indebted for their supplies to the neighbouring cities of Tyre and Sidon. Even in Greece itself, glass was by no means ancient. In the days of Homer it was unknown. Herodotus, indeed, mentions its employment for ear-rings, but these may have been of Phœnician fabric. It was called *hyalos*, crystal or ice, and *lithos chyte*, or fusible stone. Aristophanes, 450 B.C., mentions glass or crystal vessels, and various inscriptions confirm its use, but its value was next to gold, which could hardly have been the case if it had been of native manufacture. In the 4th c. B.C., Pausias, a celebrated painter, had depicted *Meke*, or 'Intoxication,' drinking from a transparent glass bowl which revealed her face. Glasses and plates, amphore and diotæ, large two-handled jars, were made of it, and also false stones for finger-rings, called *sphragides hyaleni*. These last, called by archaeologists *pastes*, were imitations of engraved stones in coloured glasses, used for the rings of the poorer classes, and were no doubt often copies or impressions of engraved stones of celebrated masters; false gems and camei having a subject in opaque white, sometimes like the sardonyx, with a brown layer superposed on the parts representing the hair, and the whole laid on a dark-blue ground, appear before the Christian era. Lenses were also made of glass, and the celestial sphere of Archimedes was made of the same material. The supposed Phœnician coloured glass vases for the toilet, found in the oldest sepulchres of Greece, it must be observed, have Greek shapes. Glass-makers, *hyalopsai*, *hyalepæ*, are also mentioned

at a later period, when there can be no doubt the art was practised. Of the Alexandrian glass, mention has been already made; and the body of Alexander the Great was shown to Augustus in a glass coffin.

The glass-making art in Italy does not date earlier than the commencement of the Roman Empire, importations from Sidon and Alexandria having previously supplied the want of native manufacture, but there is ample evidence of its extensive manufacture at that period having been introduced in the days of the Ptolemies, large plates being used for incrusting chambers, *vitrea camere*; and hollow columns, made of this material, with lamps inside, were used to illumine the public theatres. As early as 58 B.C., the theatre of Scaurus had been decorated with mirrors or glass plates, disposed on the walls. Glass was also used for paving, and for the blue and green tesserae of mosaics (see MOSAIC). Window-glass does not appear till about the 3d c. A.D., the houses at Herculaneum, destroyed in the reign of Titus, being glazed with talc, and some doubt remaining as to the use of glass for this purpose at Pompeii. Lactantius in the 3d c. A.D.; St Jerome, 422 A.D., mention glass windows. Older windows of this material are said to have been found at Ficulnea, and even in London. Under the Romans, coloured as well as

Fig. 2.—Moulded Glass Roman Cup, with the Circus and Gladiators, found in London.

white glass was extensively used; it had a greenish tint in the first days of the Empire, but had sensibly improved in colour and quality in the days of Constantine. The first production of a white glass like crystal was in the days of Nero. Its use was most extensive, and it was either blown or stamped according to the objects required. Glass vases, *vasa vitrea escaria potoria*, are mentioned. So are costly cups of many colours, purple ones of Lesbos, and balsamarii, especially the kind long called lachrymatories, which held perfumes, medicine, drugs, and other substances like modern vials, ampours, ampullae, pillar-moulded bowls, bottles for wine (*lagenae*), urns (*urnae*) for holding the ashes of the dead, and pillar-moulded bowls or cups (*pacula*).

Besides these articles of amusement and luxury, hair-pins, beads, rings, balls, draughtmen, dice, knuckle-bones (*astragali*), mirrors, multiplying-glasses, prisms, magnifying-glasses, telescopes, and water-clocks were made of this material.

Many vases are stamped, and some, principally of square shape, have the initials and devices of their makers or contents, as eye-waters, impressed on the bottom. Most of the precious stones were successfully imitated in glass pastes; and the Empress

Salonina was egregiously cheated by a fraudulent jeweller. But the most remarkable works in glass are the camei vases (*toreumata vitri*); of which the most celebrated is the Portland vase in the British Museum, a two-handled vessel about 10 inches high, of transparent dark-blue glass, coated with a layer of opaque white glass, which has been treated as a cameo, the white coating having been cut down, so as to give on each side groups of figures delicately executed in relief. The subject is the marriage of Peleus and Thetis, and the urn held the ashes of a member of the imperial family of Severus Alexander, who died 221—235 A.D. This emperor had imposed a tax upon glass. It was found in a magnificent sarcophagus in the Monte del Grano, near Rome. A vase of

Fig. 3.—Portland Vase.

smaller size, but of similar fabric, with arabesques, found at Pompeii, exists in the Naples Museum; and numerous fragments of even finer vases, some with five colours, exist in different museums. In the reign of Tiberius, an adventurer pretended that he had invented flexible glass, and threw down a vase which only bent, and which he readjusted with a hammer; he seems to have connected it in some way with the philosopher's stone, and the emperor is said to have banished him or put him to death. This invention is said to have been twice reinvented in modern times—once by an Italian at the court of Casimir, king of Poland. In the 3d c. A.D. appeared the *diatrata* or 'bored vases,' consisting of cups (*pacula*) having externally letters, and net-work almost detached from the glass, but connected by supports; all which must have been hollowed out by a tool, involving great labour. One vase of this class, bearing the name of Maximianus, who reigned 286—310 A.D., fixes their age. At a later period, bowls of engraved glass, having subjects of gladiatorial fights, came into use. Still later, apparently in the 5th c., a new style of glass ornamentation was introduced, consisting of the figures of Christ and legends of saints, and the portraits of private persons laid on in gold upon one layer of glass, over which was placed another through which they appeared. At the close of the Byzantine Empire, the glass art was still rich and ornamental. Achilles Tatius describes a vase which, when filled with wine, made the portion representing the bunches of grapes seem red, as if ripened by the autumn. The numerous beads called serpents' eggs or adder stones (*glain nardryr*), found throughout Roman Britain, were imported by route of Gaul to Britain, or made in Britain. Glass was cheap under the Roman Empire, and Strabo informs us that in his days in Rome a glass cup and saucer only cost an *as* (about a half-penny). Such articles, indeed, can only have been of the commonest kind, as Nero is said to have paid 6000 sesterces, or about £50,000, for two cups of moderate dimensions. Aurelian made the Alexandrians pay a tax of glass. A peculiar white glass seems to have been made at Carthage under the Roman empire. Glass gems for rings (*vitrea gemmae*) were in most extensive use. Glass, however, was considered always something costly and rare, and is mentioned as

such in the *Revelations* and in the *Recognitions of St Clement*, in which St Peter is described as praying to see some marvellous columns of this material in the island of Aradna. At the close of the Roman Empire, only two kinds of glass appear to have been manufactured—bottles of a greenish glass in the west, and the *Ayalina diachrysa*, or gilded glass of many colours, in the east. After that period, a few glass vessels have been found in the Anglo-Saxon graves of England, and Frankish sepulchres of France, of a peculiar fabric of green glass with projecting knobs, bent round to the body of the glass, and apparently a rude imitation of the *diastreia*. The Romans knew the use of soda and lead as fluxes for glass, and made both crown and flint glass. They made most of the fancy varieties at present in use, and were acquainted with the art of colouring it blue by cobalt, green by copper, rose or ruby by gold. Many of their imitations of gems and other fanciful colours were also of *Schmeltz* glass. But the great site of the glass manufactories of the dark and middle ages was Venice, whither it was transplanted on the foundation of that city in the 7th c. A.D. The art, however, seems to have improved on the conquest of Constantinople by the French in 1204, and in 1291 the establishments were removed to the island of Murano, the manufacturers forming a guild with a *libro d'oro*, or register of nobility, and the secret kept with the greatest jealousy. In 1436, their colour-glass came into note, and continued so till the close of the century; and in the 16th c., lace-patterns and mirrors were introduced. In the 15th and 16th centuries, plain glass with nice ornaments gilt and enamelled; in the 16th, crackled lace and reticulated glass, *vitrodi triso*; and in the 17th c., variegated or marbled glasses were

to England, and transported to Africa and Asia in the way of trade. The Venetian glass engaged for a long time the monopoly of commerce, their mirrors, goblets, and cups being exported all over the world, but it has been superseded by manufactures of England and Germany. The forms of the Venetian glass reflected its oriental origin, and the earlier glass of other countries of Europe in their turn shew the derivation of their art from Venice. In Germany, the oldest glass (which was flint) dates from the 16th c., and consists of goblets and tankards of white colour, enamelled with coloured coats of arms and other devices, *millefiori*, and *schmeltz* glass. Engraved glass was first introduced by Caspar Lehmann at Prague in 1609 under imperial protection, and continued by his pupil G. Schwanhard; and ruby glass by Kunckel in 1679. Glass is said to have been made in 1294 at Quinquagnone, in Normandy, before the 16th c., in the reign of Philip VI.; and John and the Dukes of Lorraine established manufactories in their domains, and a common kind was made in Dauphiny and Provence. Cast plate is also said to have been established at Cherbourg by artists from Venice, and in 1688 the art was declared noble. Potash, lime, silica, and no lead was employed. Thevart introduced glass casting and plate-glass works at Paris. In France, oxide of lead flint-glass was made at St Cloud in 1784; another manufactory was subsequently established at St Louis in 1790; and the St Cloud establishment was removed to the vicinity of the Mont Cenis, where it flourished till 1827. It is uncertain whether glass was made in England before the 16th c., as that mentioned may have been imported from Flanders or Venice. Window-glass is mentioned by Bede in 674, but was not in general use for windows till the 15th century. In 1557 flint-glass was manufactured at the Savoy and Crutched Friars; in 1565, there were glass-works under Cornelius de Launoy; and in 1567, Jean Quarre and other Flemish manufacturers established works at Crutched Friars, which Quarre's descendants extended to Sussex. In 1615, Sir R. Maunsell obtained a patent for making glass, in consideration of using pit coal instead of wood, and oxide of lead was then introduced in 1635; and in 1673, Venetian artists, brought over by the Duke of Buckingham, manufactured mirrors of plate-glass at Lambeth, and drinking-glasses were made at this period. But Venetian glass was extensively imported. In 1771, the company of British Plate-glass Manufacturers was established at Ravenhead, near Prescott, Lancashire; and in 1728, plate-glass was made by the Cooksons at South Shields, and the Thames Plate-glass Company in 1835—1836. Patent plate was first made in 1840. In Scotland, the manufacture was introduced in the reign of James VI., and George Hay obtained a patent for 31 years. The first glass was manufactured at Wemyss, in Fifeshire, afterwards at Prestonpans and Leith. In 1661, only the principal chambers of the king's palace had glass. In America, attempts seem to have been made to establish glass-works in 1746 at Jamestown, Virginia; subsequently, in 1780, at Temple, New Hampshire; in 1789, at Newhaven; and in 1809, at Boston. Plate-glass was first made there in 1853. It is made at Boston, Baltimore, and New York.

At an early period the application of glass for magnifying lenses appears to have been known. Ptolemy II. had a telescope mounted at the Pharos, and globes filled with water were in use for the purpose of magnifying under the Romans. Lenses are mentioned in the 12th c. A.D. by Alhazan, and by Roger Bacon in the 13th c.; towards the close of which, Salvino d'Armato invented eye-glasses, which were subsequently improved by Alexandre

Fig. 4.—German Drinking-glass.

Fig. 5.—Venetian Glass on open-work stem.

produced. The *millefiori* glass extends through all periods, and seems to have been derived from the Roman, being continued to the present day, when large quantities of this glass are annually imported

Spina. Within the present year (1862), glass-reflectors for telescopes, of great size and accuracy, have been made in France. See TELESCOPE.

As regards processes of making, that called the cylindrical was used by the ancients, and is mentioned by Theophilus at the end of the 12th century. The rotatory process was first introduced in Bohemia, subsequently into France in 1730, but not into England till 1832. Pressed glass was invented in America. In England, the tendency has been to throw the trade into fewer hands, there having been 24 window-glass factories in 1847, and only 8 in 1858; but the value of the export increased from £26,694 in 1848 to about £500,000 in 1855.—Franks, A. W., *Vitreous Art in the Art Treasures of the United Kingdom* (Manchester) *Exhibition* (4to, 1858); Pellat, A., *Curiosities of Glass-making* (4to, Lond. 1849); *Exhibition of Works of Industry of all Nations* (1851); Reports of Juries (1852), CL xxiv. p. 521.

Manufacture.—The manufacture of glass, as at present carried on, may be classed under the following heads: Bottle-glass, Crown Window-glass, Sheet Window-glass, Plate-glass, Flint-glass, Coloured-glass. The first is the coarsest kind in common use. In this country, it is made generally of soap-makers' waste (which contains a quantity of soda-salts), fresh-water river-sand, brick-dust, calcined-lime, and marl; to these a quantity of *cullet*, or the broken glass of the works, is always added at a certain stage of the manufacture. This is the mixture employed in making what are called *black bottles*, used for wine, beer, &c. Of late years, light-green coloured glass has been preferred for many purposes, such as medicine bottles, soda-water bottles, &c. This colour is commonly produced by adding a large proportion of the *cullet* of crown-glass, which, by its light colour, dilutes the darker material; if, however, it is wanted of a finer quality, it is made of sand of a light colour, containing only about two-tenths per cent. of the oxide of iron. To 50 parts of this sand are added 20 parts of heavy spar (*Sulphate of Baryta*), 30 parts of soap-makers' waste, and about two-tenths per cent. of oxide of manganese.

In France, kelp and wood-ashes are used to furnish the alkaline portion of the mixture; in other respects, the material is essentially the same. In Germany, where a rich brown tint is in fashion for bottles for the light-coloured Rhine wines, the materials consist of a light-coloured clay, 16 parts; a light yellow-coloured sand, 20 parts; kelp, 8 parts; wood-ashes, 38 parts; *cullet*, 15 parts; and oxide of manganese, 3 parts.

One of the first essentials to a successful manufacture of glass, is the preparation of the melting-pots. These pots are composed of clay, which is required to be as free as possible from lime and iron. A clay obtained from the carboniferous shales of Worcestershire, in the neighbourhood of Stourbridge, is the most esteemed for this purpose; it consists of pretty nearly equal proportions of silica and alumina. The clay is carefully dried and sifted, after which it is mixed with hot water, and worked into a paste; it is then transferred to the kneading-floor, and when sufficiently kneaded—which is done by men treading it with naked feet—it is laid in large masses in a damp store-cellar to ripen, a process the theory of which is not well understood. When required for forming the pots, a sufficient quantity is taken and again kneaded with one-fourth of its quantity of the material of old pots, which are ground to fine powder and carefully sifted; this material gives firmness and consistency to the paste, and renders it less liable to be affected by heat. The pots are of two kinds, the open (fig. 6)

and the covered (fig. 7). The first is used for melting common glass, such as window and bottle glass, the other for flint-glass. In each case, the pots are

Fig. 6.

Fig. 7.

made by hand, and require great skill and care. The bottom is first moulded on a board. When the bottom is finished, the workman begins to build up the side of the pot by first forming a ring of the same height all round, taking care to round off the upper edge to a semicircular curve of great regularity; upon this he begins bending over other lumps of the paste until another equal layer is formed, and these are continued until the pot is complete; but the workmen do not work continuously at each pot until it is finished, they leave off from time to time, spreading wet cloths over the edge when they discontinue working. This is necessary, to admit of a certain amount of drying, otherwise the large weight of clay used would prevent the form from being kept, and the pot would fall to pieces, or lose shape seriously, the building of the pot is consequently extended over several days. Those made in the form of fig. 6 are from three to four inches thick, but the flint-glass pots are only from two to three inches. After the potter has finished his work, the pots are removed into the first drying-floor, where they are only protected from draughts, so that the drying may be conducted with the greatest possible uniformity. When they have progressed sufficiently, they are removed to the second drying-floor, which is heated with a stove, and the drying is here completed. They are then placed in the store, where usually a good stock is kept on hand, as time improves them, and they are seldom kept less than six or nine months. When required for use, they are placed for four or five days in the annealing furnace, which is on the reverberatory principle, and they are there kept at a red heat. This furnace is so situated, that the pots, when ready, can be most quickly transferred to the main furnace—an operation of exceeding difficulty, and requiring great skill and dexterity, as they have to be removed whilst red-hot, and it must be done so quickly that no sudden cooling shall injure the pot, a difficulty which can only be understood by remembering that the ordinary pots are nearly four feet in depth, are the same in width at the mouth by about thirty inches at the bottom, and they weigh several hundredweights. The enormous amount of labour bestowed upon these pots makes them very expensive, their value being from £6 to £10 each. Their removal from the annealing oven to the main furnace is effected by an immense pair of forceps several feet in length, which are placed horizontally upon an upright iron pillar about three feet in height, which rises from a small iron truck on four wheels, so that the whole apparatus can be easily moved from place to place. By means of this instrument the pot is lifted and dexterously withdrawn from the oven, and as quickly transferred to its position in the main furnace, in which usually four or six are placed on a platform of firebrick or stone, each pot being opposite to a small arched opening, through which it can be filled and emptied.

The entrance to the main furnace, through which the pots have been introduced, is then closed with a movable door of firebrick, and covered over with fireclay, to prevent the escape of heat; the pots in the furnace are filled with the prepared materials for glass, now called *frit*, mixed with about a sixth or eighth part of cullet or broken glass; the openings are closed temporarily for two or three hours, by which time the first charge of material has melted down, leaving room for a further supply, which is then thrown into the pot, and this is repeated two or three times until the pot is completely full. The openings are then closed, and the heat increased to the utmost for ten or twelve hours: this part of the operation is called *founding*, and the result of it is to perfectly melt and vitrify the materials. The heat of the furnace is now somewhat reduced, and the scum is removed from the surface of the melted material, now technically called *metal*, by a workman called the *skimmer*, whose labour requires great care and much experience, as the metal is at a glowing white heat, and is only with difficulty distinguishable in the fierce white glare of the furnace. The metal is now ready for the commencement of the *journey*, as the operation of working it up is called. This term, like most others in the glass trade, is derived from the French.

The arrangements so far apply equally to all kinds of glass. We now, however, return to the manufacture of glass bottles, in order the more fully to understand which, we give the following ground-plan of one of the *houses* in which this is carried on (fig. 8). *a* is the main furnace, which in this case

Fig. 8.

is square, and made to hold only four pots; at each corner is an opening, which allows the fire to enter four small reverberatory furnaces, *b, b, b, b*, called *arches*; two are called the *coarse arches*, and the others the *fine arches*. In the two former, the soap-makers' waste is calcined at a red heat for at least four hours, or whilst a set of pots is being worked out—that is to say, one journey. Then the calcined material is ground and sifted in the grinding and sifting house, *h*, after which it is mingled with the sand, &c., and transferred to the fine arches, where for the term of another journey it is again calcined. At the end of that time, the pots being empty, are refilled with this material.

When the furnaces are opened for a journey, the skimmer first removes the scum, and makes the

way clear for the *blower* and *moulder*, who takes his blow-pipe of iron, six feet in length, the part held in the hand being guarded by a covering of wood and other non-conducting materials. After heating the end of the blow-pipe in the furnace mouth, he dips it into the pot, and turning it round, gathers as much metal on the end as is sufficient to form a bottle of the size required. Usually, in bottle making, one gathering suffices, but in larger operations, such as blowing window-glass, more gatherings have to be made. The operator then blows gently down the pipe, and having thus slightly distended the bulb of red hot plastic glass (fig. 11, *a*), he takes it to a plate of polished iron, forming a low bench called the *maver*, or *mavering table*. On this he turns it round, moulding the round lump of glass into a conical form, the change being represented in fig. 11, *b*. This operation, called *mavering*, is performed in all cases where glass is blown; and as it is necessary that the glass should be pretty firm before mavering, it is often cooled by sprinkling with water, and even, as in the case of window-glass and other large blowings, turning it in a cavity containing water, which is made by hollowing out a block of wood, usually, if attainable, that of the pear-tree, which is said to be best for the purpose.

After being mavered, the glass is held to the mouth of the furnace, and the operator blows down his blow-pipe, and further distends his glass. Formerly, he commenced moulding it into the form of a bottle with his shears, one arm of which was of charred wood, and the concave bottom was made by pushing a little piece of glass, called a *punty*, at the end of an iron rod called the *pointel*; the blow-pipe was then detached by a slight blow of the shears, and the partly formed bottle was left at the end of the *pointel* attached by the *punty* in the hands of a boy who attends upon the man, and brought and applied the *punty*. The man then took the *pointel* in one hand, and after softening the bottle in the mouth of the furnace, moulded the neck by means of his shears, regulating the size of the opening by means of a small brass mould, the size and shape of a cork, attached to the middle of the shears; heating the neck again, he formed with a small portion of metal from the pot the ring round the mouth of the bottle. Now, however, after mavering, and the first slight blowing, the operator inserts the glass into an iron or brass mould, which is formed in two pieces, opening or closing by the pressure of the foot on a lever. When the mould is closed, he blows down the pipe, and the bottle is completed all but the neck, the ring of which has to be formed by the addition of a fresh piece of metal, as before described. By this process, bottles are made with wonderful rapidity and exactness. At this stage of the manufacture, by either process, the bottles are taken from the workman by a little boy, who inserts the prongs of a fork into the necks, and carries them to one of the annealing arches, *d, d, d, d, d, d*, where they are carefully arranged in proper bins until the arch, which usually holds 144 dozen, is full; it is then closed, and the heat is raised nearly to melting point, and then allowed gradually to subside until it becomes cold, when the bottles are removed to make room for a fresh charge. In the plan, fig. 8, *e* and *f* are the sand and alkali stores; *g, g*, are stores for the prepared frit; and *i, j*, are sifting-cribs in the sifting-house.

Window-glass, whether *crown* or *sheet*, is made of much more carefully selected materials. They are slightly varied by different manufacturers, but the following are the ingredients used in one of the

largest glass-houses in Great Britain: Sand (well dried), from the neighbourhood of Leighton Buzzard, in Bedfordshire; sulphate of soda, ground; subcarbonate of soda, white oxide of arsenic, manganese, Welsh anthracite, chalk; limestone from Hopton Wood, Derbyshire; nitrate of soda; cullet, about as much as is equal to an eighth part of the other ingredients. The exact proportions are only known to the manufacturers. Each ingredient is carefully powdered before mixing, and they are afterwards calcined or fritted, except the anthracite, which is added in the pot for the purpose of decomposing the sulphate of soda, and dissipating its acid; and the manganese and arsenic, which are only added in very small quantities, to improve the colour; too much, however, of each is sure to injure the glass, and therefore these materials can only be safely used by experienced manipulators. The bulk of the glass, however, consists of the sand, and carbonate and sulphate of soda.

The arrangement of the window-glass houses is different, and on a much larger scale than in the houses for bottle-glass, and excepting in gathering and maving, all the operations subsequent to the founding are different. Fig. 9 will give a general

Fig. 9.

plan of the house for crown window-glass, and fig. 10 gives an elevation of one side of the main furnace, with the three openings through which the glass is gathered from the pots. In fig. 9, *a* is the main furnace; *b, b'*, two flashing furnaces; the projecting piece of brick-work, *b'*, being the screen which protects the workman from the fire; and *c, c* are two annealing furnaces or ovens.

When the founding or melting and the skimming are completed, the workman takes his blow-pipe, which is about seven feet in length, heats it at the end, and dipping it into the pot of melted glass

Fig. 10.

or metal through the opening (*a*, fig. 10), he *gathers*, by a slight turn or two, a quantity of glass, about a pound and a half in weight; this he withdraws,

and after turning it about for a minute or two in the air until sufficiently cooled, he then dips it in again, and over the first he makes a second gathering, which increases the weight to about three pounds weight; the same cooling process is repeated, and a third gathering is made, which brings up the weight to about nine pounds; he then holds his blow-pipe perpendicularly with the glass downward, so that it may by its own weight pull downward from the pipe in the form of a symmetrical pear-shaped bulb; he next takes it to the hollowed block before mentioned, and turns it round in the water placed in the cavity by which it is made ready for the maving table. The workman, by skilful management, *maves* the bulb of glass into the form *b*, fig. 11, and then forms a little knob at its apex, by turning it on a fixed bar of iron called the *bullion bar*; he then commences blowing, and soon the bulb of nearly solid glass is expanded into a large hollow sphere (*c*, fig. 11), still, however, with the little nipple made by the bullion bar. A little boy now comes forward with an iron rod, the *pointil*, upon the end of which has been gathered a small lump of metal, called the *puntty*, about the size of a hen's egg, this he applies to the nipple, to which it firmly adheres, the workman meanwhile resting his blow-pipe on a fixed rest called the *casier-bar*, placed for the purpose; by the pressure of the pointil the globe of glass is flattened as in *d*, fig. 11. The application

Fig. 11.

of a piece of iron, cooled for the purpose by keeping it in water, to the junction of the glass with the blow-pipe, detaches it instantly, and the globe of glass is now held with the pointil. The operator carries it next to the nose-hole (*b*, fig. 10), and presents the opening formed by the detachment of the blow-pipe, to the action of the furnace; this again softens the glass, which is kept continually revolving by turning the pointil on an iron rest or hook fixed to the masonry of the furnace. The revolutions are at first slow, but are gradually accelerated as the softening of the glass goes on, and the centrifugal force so produced throws the edges of the orifice outwards, as in *e*, fig. 11. As the glass flattens, it is revolved with greater rapidity, and advanced so near to the mouth of the nose-hole as to draw the flames outward, by contracting the draught. This completes the softening of the glass, which is done suddenly, with a rushing noise like the unfurling of a flag in the wind, caused by the rapid flying outward of the softened glass and the rush of the flames outward. It becomes perfectly flat, and of equal thickness, except at the bullion or centre, formed, as before described, by the bullion-bar and the puntty. The *flashing* is now complete; and the workman removes it from the nose-hole, and still continuing to turn it in his hands, in order to cool and harden it, as he walks along, carries it to the annealing oven, where another one receives it on a large flattened fork-like implement at the moment the *flasher*, who has hold of the pointil, suddenly detaches it by a touch of his shears. It is then passed through the long horizontal slit which forms the opening into the annealing oven, and when fairly in, it is dexterously turned on

its edge; here it remains at a temperature somewhat below that required to soften glass, until the oven is filled with these so-called *tables of glass*, when the heat is suffered to decline, until the whole is cold, when they are removed to the packing-room, to be packed in crates for sale.

Until lately, crown-glass was almost universally employed for windows, but now that which is called *German sheet* has become quite as common, besides which *British sheet*, which is the same glass polished, and *plate-glass* are much used. The operation of making the sheet-glass is very different from that employed in making crown-glass, inasmuch as a long and perfect cylinder is sought to be produced by the *blower* instead of a sphere of glass. This necessitates also a different arrangement of the glass-house, as is seen by the ground-plan shewn in fig. 12: *aa* is the furnace, *b* is the annealing oven,

Fig. 12.

heated by the fire *V*, which opens into the main furnace; the *leer*, or annealing oven, is often, however, an independent structure; *c, c, c, c, c, c, c, c*, are the eight pots, which is the number usually employed in these works. These, of course, are opposite to the openings for working them, and in front of each opening is a long opening in the ground, about eight feet deep and three feet in width; *d, d, d, d, d, d, d, d*. The workman stands on the edge of this pit, and having made his gathering, as in the crown-glass manufacture (*a*, fig. 13), he next *movers* it, without, however, using the bullion-rod (*b*, fig. 13). He next proceeds to blow his glass, holding it downward whilst doing so, that its weight may widen and elongate the bulb, and from time to time dexterously swings it round, which greatly increases its length (*c, d*, fig. 13). As it cools rapidly in this operation, he from time to time places his pipe in the rest which is fixed before the furnace-mouth, and gently turning it round, he brings it again nearly to the melting-point, then he repeats the blowing and swinging, standing over the pit, to enable him to swing it completely round as it lengthens out. These operations are continued until the cylinder has reached its maximum size, that is, until it is of equal thickness throughout, and sufficiently long and broad to admit of sheets of the required size being made from it (*e*, fig. 13). Sometimes these cylinders are made 60 inches in length, allowing sheets of glass 49 inches in length to be made from them. The next operation is to place the pipe in the rest, and apply the thumb so as to close

the opening at the blowing end; the heat of the furnace soon softens the glass at the closed extremity of the cylinder, and as the enclosed air is prevented escaping, as it rarefies, by the thumb placed on the opening of the blow-pipe, it bursts at the softened part (fig. 13, *f*); the operator then quickly

Fig. 13.

turns the cylinder, still with its end to the fire, and the softened edges of the opening, which at first are curved inwards, are *flashed* out until they are in a straight line with the sides of the cylinder (*g*, fig. 13). It is then removed, and placed on a rest or casher-box, when a small punty of melted glass at the end of a pointil is brought by a boy; this the workman applies to one side of the cylinder, just below the shoulder formed at the blow-pipe end (fig. 13, *g*), and drawing it out to a thin string, wraps it quickly so as to draw a line round the cylinder; after a second or two, he withdraws this line of red-hot glass, and touching it quickly with his cold shears, the shoulder and neck drop off as neatly as if cut with a diamond.

The cylinder (fig. 13, *h*) is now placed for a short time in the annealing oven (*b*, fig. 12), where it is prepared for cutting; it is next placed in a groove lined with green baize, and a diamond fixed to a sliding rule makes a perfectly straight cut from end to end. The split cylinder is then taken to the *flattening* arch or furnace, where it is laid on the bottom, with the diamond-cut upwards. The bottom is a perfectly smooth stone, kept constantly free from dust by the workman; here the heat is sufficient to soften without melting the glass, and the *flattener*, as it softens, opens the two edges of the crack until they fall outward flat on the stone; he then takes an implement in the form of a rake, made by placing a piece of charred wood transversely at the end of a long handle, and this is gently rubbed over the glass, producing a very smooth surface. At the back of the flattening arch is an annealing oven, communicating with the arch by a narrow horizontal slit, through which the sheet of glass is now pushed on to a plate of iron, which receives it; and as this plate is one of a series linked together so as to form an endless band, which can be turned round, the sheets move forward into the annealing oven, where the workman gently lifts them on edge until the oven is filled, when, as in the case of crown-glass, the heat is allowed to decline until perfectly cool, the sheets are then ready for use. Very much larger sheets are obtained by this process than by the former one, hence it is becoming of great importance; but it is not easy to obtain workmen sufficiently powerful and dexterous to blow and twirl the largest-sized cylinders; at present, we obtain almost all the operatives so employed from Belgium.

Glass-shades are made in the same manner as above described; indeed, they are nothing more than the rounded ends of the cylinders before being burst. When wanted oval or square, these forms are produced by boxes of wood charred inside, of the size the shades are required, through which the

GLASS.

cylinder is passed when being blown, until the soft glass touches, and receives shapes from the inside of the box or mould: they are afterwards annealed, and cut to the lengths required. If of large diameter, they require immense strength and great skill in the operator, who sometimes aids the power of his breath by taking into his mouth a little spirit, which he blows down the pipe; this, of course, is instantly converted into vapour, when it reaches the red-hot cylinder, and by its expansion aids in distending the glass.

Plate-glass is made in a totally different manner; and as its value depends chiefly on its purity, the greatest possible care is taken to procure materials

of the best quality, and almost every manufacturer has his own private formula for the mixture. It may, however, be said to consist chiefly of sand and alkaline salts, as in other kinds of glass, and the following is one receipt known to be in use: Fine white sand well washed, to free it from impurities, 720 lbs.; sulphate of soda, 450 lbs.; slaked lime, 80 lbs.; nitrate of potash, 25 lbs.; and cullet of plate-glass, 425 lbs. These ingredients, when melted and skimmed, should yield about 1200 lbs. of perfectly clear metal, which is the quantity usually required for a casting. When melted and ready for use, the pot is lifted out of the furnace (*aa*, fig. 14) by means of the forceps, and wheeled up to the casting-table

Fig 14.

(*aa*, fig. 14); here it is seized by a crane and tackle, by which it is lifted, and so nicely poised over the table, that it can be easily tilted so as to pour out its contents. All this requires so much care and steadiness, that the men, impressed with the great danger of carelessness, usually preserve perfect silence during their work. The table is of large size—20 feet or more in length, by 8 or 10 feet in width. When the red-hot liquid glass is poured on, it immediately begins to spread; two bars of iron, a little thicker than the plate is intended to be, are quickly laid on each side of the table, and a steel roller is laid across, resting on these bars: this roller is worked by hand, and rapidly spreads the glass all over the table, the bars preventing it from running over the sides, and regulating its thickness. In a very short time, it begins to cool; the men then seize the end of it with pincers, and pull it forward with great dexterity on to an endless band of wire-gauze, which, being made to revolve, moves the immense plate forward to a slit-like opening to the annealing oven (fig. 14, *ff*), where it is worked on to another table on wheels, which is pushed forward to make room for another. The annealing oven is usually of immense length, as, in the case of plate-glass, the sheets cannot be set on edge. At the works at St Helen's, in Lancashire, where glass of all kinds is extensively made, there are usually two annealing ovens to each shed, the furnaces being placed between them; each oven runs to the end of the shed, and these sheds are usually over 300 feet in length. The ground-plan shewn in fig. 14 will give a general idea of the arrangement of one of these vast work-shops. The main building is a shed, with the doors at each end, and both doors and windows are made so as to exclude drafts of air, which, if admitted during the operation of casting, are highly injurious to the quality of the manufacture. *a, a*, are the two melting-furnaces; *b, b, b, b, b, b*, the pots; *c, c*, the casting-tables; *d, d*, the endless bands of wire-gauze for moving the plates to the annealing ovens; *e, e*, where they enter

by the narrow openings, *ff*; and, after they have sufficiently cooled, are removed through the openings at each end, *g, g*.

The plates are next removed to the first polishing-shed, where each is imbedded in a matrix of stucco, leaving one surface exposed; the whole is enclosed in a frame, which holds both glass and stucco securely. Two of these frames are placed one over the other, with the two exposed surfaces of glass in contact. The lower frame is fixed, and the upper is made to move by machinery with great rapidity backward and forward with a swinging motion, so as to describe an opposite curve with each backward and forward motion. Sand and water are continually thrown on the surface of the fixed plate, and thus the first stage of polishing is performed. The plates are then readjusted in the frames, and the other surfaces are brought upwards, and receive a similar rubbing down with sand and water. The plates are next removed to the second polishing-room, where women are usually employed; here they are again fixed on low tables, and each woman rubs the surface for a long time with a piece of plate-glass, covering from time to time the whole face of the plate with emery-powder and water. After both sides have received this hand-polishing, the plates are removed to a third room, where they are again imbedded on tables which are movable by machinery, so that the whole surface of the plate may be brought under the action of the polishers. These are large movable blocks, covered with woollen cloth and leather, and loaded so as to press on the glass; the polishing material used is colcothar, the red oxide of iron; this completes the polish which gives so much beauty to plate-glass. It is a long and laborious process, and is the chief cause of the high price of plate as compared with other sheet-glass. British plate is only the cylinder glass polished by the processes just described; its comparative cheapness is due to the rapidity with which the cylinder can be blown. Of this rapidity, the best estimate may be formed from

GLASS.

a single well-authenticated statement concerning the first Crystal Palace, which had 18 acres of roof; when the sides are added to this, and a fair addition for the increase caused by the ridge-and-furrow system of the roof, the whole extent may be stated at 25 acres; and yet this vast surface of glass was supplied by Messrs Chance & Co. of Birmingham, with only an interruption of three weeks to their ordinary business.

Flint-glass and Optical Glass.—The general principle of the manufacture of these two varieties of glass is identical with those already described, the chief difference consisting in the great care taken to insure perfect purity in the materials. The pots used are so made, that the metal is protected from the chance of being contaminated by any accidental impurities falling in or from the gases of the furnace; they are made with a dome-shaped roof and a lateral arch-shaped opening (fig. 7), which is placed opposite the furnace-mouth, so that the workman has easy access to the contents of the pot, which is necessarily smaller, otherwise the workman could not dip to the bottom.

The materials used for the best *flint-glass* are varied in their proportions, according to the judgment of the manufacturer; they consist of the whitest sand which can be procured, fine American pearl-ashes (impure carbonate of potash, which is purified by dissolving out the carbonate from its impurities, and evaporating it to dryness in leaden evaporating pans), red lead, or else litharge (the semi-vitrified protoxide of lead), and a small quantity of nitre (nitrate of potash). To these, according to their greater or less purity, the manipulator adds more or less of oxide of manganese and arsenic, as correctives; the former removes the green discoloration which the presence of even a small quantity of iron in the sand will produce; and the latter corrects the tendency the manganese has to give a purple tint to the glass. Both substances require the utmost care and judgment in their use, otherwise they are more injurious than beneficial. The following are the usual proportions: Sand, 51; pearl-ashes, prepared, 16; litharge, 28 (or red lead, 29); nitre, $4\frac{1}{2}$; white arsenic, $\frac{1}{2}$; peroxide of manganese, $\frac{1}{2}$; cullet of flint-glass in any proportion the manufacturer thinks proper.

Formerly, the silica was obtained by calcining flints, hence the name applied to this kind of glass, but now sand is used instead; and although beautifully white sands are obtained from Lynn, in Norfolk, from the Isle of Wight and other parts of Hampshire, from Aylesbury, from France, and even from North America and Australia, it nevertheless requires most careful preparation by washing, calcining, and sifting.

But however carefully flint-glass is made, and however pure and transparent the crystal may be which is so made, it nevertheless possesses some defects, which interfere with its fitness for telescopes, microscopes, light-houses, and other optical purposes. These defects consist in almost imperceptible striæ in the material, which produce certain optical aberrations. These striæ are known to be caused by the imperfect mixture of the materials, and the want, consequently, of a uniform density. This has been obviated by M. Guinaud and his associate, M. Fraunhofer, by stirring the metal in the pot with an iron rod; but greater improvements have been effected by our own chemist Faraday, who not only improved upon the manipulation of Messrs Guinaud and Fraunhofer, but suggested also an improvement in the materials, by the addition of carbonate of baryta and a little carbonate of lime, which produces a glass of the greatest density and clearness that has ever been known before. Instead

of the iron rod for stirring, which of itself is apt to discolour the glass, an iron rod coated with platina is used. In the manufacture of this particular kind of glass, the Messrs Chance of Birmingham are unrivalled, and they have produced very perfect discs for lenses, weighing as much as two hundred-weights each.

Flint-glass is employed in the manufacture of all the articles of utility and ornament for table and other domestic uses; and as the manufacture of each article requires different management, it would be impossible here to give any satisfactory explanation of the manipulative processes. Suffice it to say, that at present Great Britain is unrivalled in the production of so-called crystal or flint-glass, which we manufacture of the greatest purity and brilliancy; but in the coloured kinds the Bohemians take the lead, and excel both in design and in the art of colouring.

Much flint-glass is now moulded into drinking-vessels, bottles, and other common articles; but these are always greatly inferior to those which are made by the handicraft of the regular glass-blower.

Coloured glass is a general term which includes several distinct varieties: first may be mentioned the glass made for windows and other similar purposes. Coloured sheet-glass is made both by the crown-glass and cylinder-glass processes. Sometimes it is of *pot-metal*—that is, the glass and the colouring materials are all melted and worked from one pot—generally, however, this glass is of too dark a colour, and the kind called *flushed glass* is most generally used; in this, two pots are employed, one containing the coloured glass, as if for pot-metal, the other colourless glass. The workman makes his first gatherings from the colourless glass, and the last only from the coloured pot; the consequence is that the glass when finished, although it cannot be perceived, has only a thin skin of the coloured material on one side, and the colour is thus as it were diluted. This has other advantages, because, by skilful grinding, the colour may be removed, and transparent patterns produced on the coloured ground; and the same may be done, and even delicate shading of the colour effected, by eating away the coloured side more or less by means of *fluoric acid*, which is frequently employed, and most beautiful effects are produced.

The colours usually employed consist of metallic oxides, other substances are, however, occasionally used. *Gold*, in the state called *Purple of Cassius*, invented by Dr Andrew Cassius of Leyden in 1632, and also in the state of a simple solution, without tin, yields the most beautiful ruby, crimson, rose, and purple colours. *Copper*, as a sub-oxide, yields a fine ruby red, and the black oxide gives an emerald green. *Cobalt* yields the rich deep blues. *Iron*, as a protoxide, gives a dull green; combined with alumina, it gives flesh colour, or pale rose, and combined with chloride of silver, it yields an orange yellow; as a peroxide, it gives a common red and a brownish red. *Silver*, with alumina, also yields a yellow colour of great beauty; and commoner and less beautiful yellow tints are produced by glass of antimony, and even by carbon, either in the form of soot or charcoal. *Uranium* gives the beautiful chrysoprase green and canary yellow, with a slight degree of opalescence; it also gives an emerald green. Arsenic, or arsenious acid, produces an opaque white. Manganese gives a purple or amethystine colour as an oxide; and as a peroxide, with a little cobalt, a fine garnet-red colour. There are some of the materials generally employed, but there are numerous others, the use of which depends upon the skill of the manufacturer.

GLASS—GLASS-PAINTING.

The applications of coloured glass to ornamental purposes are very numerous; one has already been fully described under the head of *GEMS, ARTIFICIAL*. In the hands of skilful glass-workers, especially those of Bohemia, articles of ornament and utility, combining the most exquisite combinations of form and colour, are produced. But not the least interesting application of coloured glass is the art of producing windows exhibiting beautiful pictorial designs. So beautiful are the designs of some of the windows formed from this material, that they deservedly rank as works of high art. This art originated at the commencement of the 9th c., and received its greatest development in the 15th century. It then began to decline, until, at the commencement of the present century, it was slowly revived, at first with but little success, a conviction having been formed that the true secrets of the art of producing the rich colours seen in ancient windows were lost. Gradually, chemistry and the microscope removed the errors, the former demonstrating the exact constituents of the best kinds of ancient glass, enabled the manufacturer to imitate it exactly. Still, however, with the same ingredients, there was a remarkable want of richness in the modern material: the cause of this was revealed by the microscope, which shewed that it was due to minute pores, which are produced by weathering of the outer surface, the alkaline parts of the glass being washed out, as it were, by the rain, &c. This porosity, by breaking up the surface, destroyed the flatness and glare of the glass, and by mixing more thoroughly the rays of light, produced that richness for which the ancient glass is so famous. Various methods were adopted to produce this effect: one which became common was, to stipple the surface with dots of a dark opaque colour; now it is still better and more ingeniously done by sprinkling sand thickly over the gathering of glass before receiving the coloured coat, so that when blown and flashed, it has the grains of sand thinly scattered through its substance, and these being refractive, very successfully produce a richness nearly equal to that acquired by age.

So far, indeed, from the art being lost, there is no doubt that a better material and better colours are now made; and those who examine the works produced by Ballantyne, Chance, and other manufacturers of our country, and those of Munich and other continental works, will not easily believe that the ancients were more successful in their designs than the moderns. But besides the pot-metal and flashed glasses before mentioned, there are two other methods of colouring and producing pictorial effects on glass. The first is by staining, that is to say, painting the glass with various materials, usually metallic oxides finely powdered, and mixed with oil of spike or some other volatile medium; the glass is then placed in a furnace, in which it is made red hot, and a deep stain of the colour required is produced on the glass. This process enables the artist to produce a complete picture on one piece of glass; whereas, by the older method, the picture had to be made up of a vast number of pieces set in a slender lead-framing. Generally, both methods are employed in pictorial windows, as the staining enables the artist to give the human features. But staining does not produce the same brilliancy of colour, and lessens the transparency of the glass, hence it is in less esteem.

Another mode of decorating glass is by using the opaque or nearly opaque enamel colours, and after the design is produced with these, to fix them by firing: this is a beautiful art, and is variously employed

Lately, another and very remarkable invention for decorating glass has been patented by M. Joubert of Bayswater, London—viz., the fixing of photographic pictures upon this material. The sensitive salt used to receive the picture is one which will stain glass; therefore, on firing, the picture is deeply burned into the glass, and cannot be effaced; most beautiful effects are thus produced; natural landscapes and pictures may be transferred with most perfect fidelity.

Glass-grinding and Engraving.—Glass can be easily ground with sand and water, so that the ornamental effect of vessels and other objects of flint-glass may be very greatly enhanced. Sand, however, leaves a rough surface, and destroys the transparency; but this is easily restored by other polishing materials, as emery, putty-powder (oxide of tin), tripoli, red oxide of iron, or colcothar, &c. The cutting and polishing are effected with wheels or discs of sandstone, wood, and metal. Very fine engraving is done with pointed metal tools and diamond-dust, the same as in seal-engraving, &c.

The polishing of lenses for optical instruments and for light-houses is an art of very great importance, requiring extraordinary skill. Much of the polishing of the larger lenses is effected by the aid of machinery, and perhaps no combinations of mechanical art are more wonderful than the machines by which the Messrs Chance of Birmingham polish the prisms and lenses for catoptric and dioptric light-houses.

Glass in a liquid form has lately been extensively made under the name of soluble glass or silicate of soda; it is silica, or sand, dissolved in a solution of caustic soda. This liquid, when used as a varnish, is said to protect stone and other materials from the injurious action of the weather, and for this purpose is now employed to arrest the decay of the stone of the new Houses of Parliament. It is also extensively used in the manufacture of soap (see *SOAP*); and this, or a similar soluble glass made with potash, has been recommended to be used as a dressing for muslins and other fabrics to render them fireproof. The soluble soda-glass has also been successfully employed in mounting microscopic objects, instead of Canada balsam or glycerine.

GLASS-PAINTING (in Art). The application of coloured glass to the artistic decoration of windows has been previously alluded to, but the very high position which it formerly attained, and which it is again rapidly approaching, renders it necessary to devote a short space to its relationship to the fine arts.

Originally, there was but one method of making ornamental glass windows, and that was to produce the pattern in outline with finely made leaden frames, into the grooves of which pieces of coloured glass or of stained glass were fitted. Modern chemistry has, however, so improved the art of glass-staining, that large pictures may now be produced on single sheets of glass, as in the case of the windows shewn by the St Helen's Crown Glass Company in the Exhibition of 1851, one of which, designed by Mr Frank Howard, representing 'St Michael Casting out the Great Dragon,' was upwards of nine feet high by three feet broad. It was on plate-glass, and had to be fired or submitted to intense heat fifteen times, notwithstanding which it was perfectly smooth, and although somewhat deficient in brilliancy of colour, was an excellent and effective composition.

One of the best known of the early applications of glass to the window decoration is that in the monastery of Tegernsee, in Upper Bavaria, which was secularised in 1802, and is now a private

residence; but these windows (executed in the latter half of the 10th c.), like all of the first attempts, were only tasteful arrangements of coloured glass in imitation of the stone mosaics used for floors, &c. Nor did the art rise much above this for at least three centuries after its origination; but in the 13th c., owing to the full development of the Gothic style of architecture, it became of immense importance, coloured glass taking the place of tapestried curtains in filling up the spaces within the groined arches. The mosaic patterns were superseded by elaborate designs, not only in beautiful arabesque and other styles of decorative art, but even pictorial compositions were attempted; and to such perfection did this arise, that many of the works produced in the 15th c. are marvels of art. In all of these, the figures, with the exception of the faces, were made up of pieces of self-coloured glass combined with great skill and taste; the features were painted in enamel colours, and burned in, and the art of the artist was shown by giving ease and grace to the figures corresponding to the expression of the faces. Gradually the art of shading, by removing certain portions of the coloured surface, and other improvements were effected. This was the culminating point in the history of the first period of the art of glass-painting, as it is called, and seemed to have attained the highest perfection of which it is susceptible, for the efforts which followed to improve it by assimilating it to oil-painting signally failed, and with this failure began that decline in the art which was perhaps more remarkable in the instance of glass-painting than in any other, for in a comparatively short time it began to be felt that the true art was lost. Since the commencement of the present century, rapid strides have been made towards improvement; and the renaissance bids fair to eclipse the glory of the first epoch. The great seats of this art are now in Munich, Nürnberg, Paris, Birmingham, Edinburgh, and one or two more places; and it never received more liberal patronage in its palmy days than it now does.

GLASS PAPER, or CLOTH, is made by powdering glass more or less finely, and sprinkling it over paper or calico still wet with a coat of thin glue: the powdered glass adheres as it dries. Glass paper is very extensively employed as a means for polishing metal and wood-work; it is sold in sheets, and is very largely manufactured at Birmingham and other places.

GLASSCHORD, a musical instrument, with keys like a pianoforte, but with bars of glass instead of strings of wire. It was invented in Paris in 1785 by a German called Beyer. The name glasschord was given to the instrument by Franklin. When the glasschord was completed, it was exhibited publicly in Paris, and performed on by the inventor; but it never was received with favour by the instrument-makers, so that no more were ever made, as possibly its construction and mechanism remained a secret with its inventor.

GLASS-CRABS (*Phyllosomata*), a family of crustaceans, of the division *Malacostraca*, order *Stomatopoda* of Cuvier, remarkable for the transparency of their bodies, whence their popular name, whilst the scientific name (Gr. leaf-body) refers to the great horizontal expansion of the carapace. They have little resemblance to crabs. The head is represented by a large oval plate, bearing eyes mounted on very long stalks, a second plate, the breadth of which much exceeds its length, represents the thorax, and bears the feet, most of which are long, and some of them, as in a few other crustaceans, bifid, with one branch much longer than the other. The abdomen

is small. Milne-Edwards supposes these creatures to have no special organs of respiration, but that the blood is aerated through the general surface of the

Glass Crab:

a, head; b, thorax; c, abdomen.

body. They are found in tropical and sub-tropical seas; and so transparent are they, that, when floating on the surface of the water, they would not be perceived but for the beautiful blue of their eyes.

GLASSITES, a religious sect, which sprang up in Scotland about 1730, when its founder, John Glas, a native of Auchtermachty, in Fife, and minister of the parish of Tealing, near Dundee, was deposed by the General Assembly of the Church of Scotland, chiefly on account of views which he had adopted and published concerning the nature of the kingdom of Christ. In his *Tamony of the King of Martyrs concerning his Kingdom*, founded on the words of our Saviour recorded in John xviii. 36, 37, Mr Glas maintained that all national establishments of religion are inconsistent with the true nature of the church of Christ, and was thus probably the first assessor of the *Voluntary* principle in Scotland. He also advocated a system of church-government essentially *Independent or Congregational*. After his deposition by the General Assembly, he became the pastor of a congregation. He died at Dundee in 1773. His personal worth and piety were acknowledged even by the most strenuous opponents of his peculiar opinions. A number of small congregations or churches were soon formed on *Glasite* principles, not only in Scotland, but in England and America, but both in England and America, the name of a follower of Glas, Robert Sandeman, prevailed over his own, and the sect received the name of *Sandemanians*. Sandeman, a native of Perth, is chiefly known from his advocacy of certain views respecting the nature of saving faith, now commonly designated *Sandemanian*, essentially consisting in representing faith as 'a bare belief of the bare truth,' which belief, however, both Glas and Sandeman, with at least their immediate adherents, regarded as the fruit of Divine grace and the work of the Holy Spirit. The G. have, since the beginning of the 19th c., decreased in numbers. In 1851, there were only six *Glasite* churches in Scotland, none of which contained very many members; and at the same date only six *Sandemanian* churches existed in England. The G. maintain the necessity of a plurality of teaching *elders* in every church, but do not require any special education for this office or separation from secular employments; they hold a second marriage a disqualification for it; they deem it unlawful to join in prayer with any one who is not a brother or sister in Christ; they observe the Lord's Supper weekly; they maintain *low-fasts* or *dnars* between morning and afternoon services, at which it is incumbent on every member of the church to be present; they are rigid in abstaining from things

strangled and from blood; and in general hold by the most literal interpretation of other Scripture rules, as concerning the kiss of charity, and the washing of the feet of fellow-disciples; they disapprove of games of chance, and of all use of the lot except for sacred purposes. Their charity, both to their own poor and to the poor of other denominations, is said to be exemplary.

GLASS-MEN were wandering rogues or vagrants, under the statutes 39 Elizabeth c. 4, and 1 James I. c. 7.

GLASSWORT (*Salicornia*), a genus of plants of the natural order *Chenopodiaceae*, having uniform hermaphrodite flowers, with a single fleshy obscurely lobed perianth imbedded in an excavation of the

Glasswort (*Salicornia herbacea*):

a, joints of stem bearing flowers; b, style; c, stamen.

rachis, one stamen or two, and a short style, the fruit a *utricle* enclosed in the enlarged perianth. One species (*S. herbacea*), a leafless plant with jointed stems, is common in salt marshes in Britain. It makes a good pickle, and is sometimes sold for this purpose. Several species grow abundantly on the shores of the Mediterranean; and as they contain a large quantity of soda, are used in making *barilla*, along with the species of *Saltwort* (q. v.).

GLASTONBURY, an ancient municipal burgh and market-town in the county of Somerset, 25 miles south-west of Bath, is built in the form of a cross, and occupies a peninsula formed by the river Brue, or Brent, called the Isle of Avalon. It has small manufactures of silk, and some export trade in timber, alates, tiles, and agricultural produce, by means of a canal connecting it with the Bristol Channel, and the railway between the Bristol and Exeter and Wilts and Somerset lines which passes through Glastonbury. Pop. (1861) 3593. The town owes its origin to its celebrated abbey, which, according to tradition, was founded in 60 A. D., and was one of the earliest seats of Christianity in Britain. Its traditionary founder was Joseph of Arimathea, and the 'miraculous thorn,' which flowered on Christmas-day, was, till the time of the Puritans, believed by the common people to be the veritable staff with which Joseph aided his steps from the Holy Land. The tree was destroyed during the civil wars, but grafts from it still flourish in the neighbouring gardens. In 605 A. D. the monks adopted the dress and rules of the Benedictine order. This magnificent pile at one time covered 60 acres; but as most of the houses in G., and also a causeway

across Sedgemoor, have been constructed of the materials, the extent of the ruins is now much diminished. The most interesting remains are the Abbey Church, with St Joseph's Chapel, St Mary's Chapel, and the Abbot's Kitchen. St Joseph's Chapel is one of the most elegant specimens in existence of the transition from Norman to Early English architecture, and is supposed to have been erected during the reigns of Henry II. and Richard I. It is now roofless, and the vaulting of the crypt is nearly destroyed. The entrance is adorned with sculpture. Below the floor is a Norman crypt, within which is St Joseph's Well. Of the Abbey Church, few fragments remain. The Chapel of St Mary is roofless, but the remains of its pointed windows and archways are exceedingly elegant. The Abbot's Kitchen, now separate from the rest of the ruins, is a square massive structure, the walls strongly buttressed, and dates from about the 15th century. G. has the honour of ranking St Patrick (415 A. D.) and St Dunstan among its abbots. In 1539, Henry VIII. summoned Abbot Whiting to surrender G. and all its treasures; and on his refusal, condemned him to be hanged and quartered, and the monastery confiscated to the king's use, which sentence was immediately carried into execution. According to tradition, King Arthur and his Queen Guinevere were buried in the cemetery of the abbey; and Giraldus Cambrensis states that 'a leaden cross, bearing the following inscription, "Hic jacet sepultus inclitus Rex Arthurus in insula Avallonia," was found under a stone seven feet below the surface; and nine feet below this was found an oaken coffin, containing dust and bones.' This disinterment took place by order of Henry II. The only other objects of interest at G. are the Church of St Benedict; the Church of St John the Baptist, with a tower of 140 feet high; the Weary-all Hill, where Joseph of Arimathea rested from his weary pilgrimage; and the Tor Hill, where the last abbot of G. was put to death. 500 feet above the sea-level, crowned by a beautiful tower, the ruin of a pilgrimage chapel of St Michael.

GLATZ, a town of Prussia, in the province of Silesia, is a fortress of the second rank, and is situated between two fortified hills, on the left bank of the Neisse, 52 miles south-south-west of Breslau. It has four Catholic churches and a Catholic gymnasium; and carries on considerable manufactures of linen, damask, and woollen fabrics, as well as of leather and rose-garlands. Pop. 10,949, including 2176 of a garrison. During the Thirty Years' and the Seven Years' Wars, G. was frequently besieged and taken.

GLAUBER, JOHANN RUDOLPH, a German chemist and physician, was born at Karlstadt, in Franconia, in 1604, and died at Amsterdam in 1668. No details regarding his life are known, except that he resided for a long time at Salzburg, then at Kissingen, then at Frankfurt-on-the-Maine, then at Cologne, from whence he probably removed to Amsterdam. Although a believer in the philosopher's stone and in the universal medicine, he contributed very materially to the progress of chemistry. Poggendorff (in his *Biographisch-literarische Handwörterbuch*) gives a list of about thirty of his works, of which a collected edition up to the date of publication appeared, in two quarto volumes, in 1658—1659, at Frankfurt, and another edition, in seven octavo volumes, in 1661, at Amsterdam. An English translation by Packe, in one large folio volume, was published in London in 1689. His name at the present day is chiefly known for his discovery of sulphate of soda, which he termed *sal mirabile*, and regarded as a universal medicine, and

GLAUBER'S SALT—GLEANNING.

a cure for all diseases.—See Kopp's *Geschichte der Chemie*, vol. i. pp. 128—133.

GLAUBER'S SALT (so called from Glauber, who discovered it in 1658) is the popular name of the neutral sulphate of soda, whose chemical composition is represented by the formula $\text{NaO}, \text{SO}_3 + 10\text{aq}$. It occurs in long four-sided translucent prisms, terminated by dihedral summits, and containing ten atoms of water. On exposure to the air, the crystals lose all their water, and become resolved into a white powder. When heated, they readily melt in their water of crystallisation; and if the heat is sufficiently continued, the whole of the water is expelled, and the anhydrous salt remains. Glauber's salt has a cooling, bitter, and saltish taste; it is readily soluble in water; its solubility (in the ordinary crystalline form) increasing up to 92°; when it appears to undergo a molecular change, and to be converted into the anhydrous salt, which at this temperature is less soluble than the hydrated compound, and separates in minute crystals. This and other anomalies which occur in the solubility of this salt have been carefully studied by Löwel (*Ann. de Chemie*, 3d ser. vol. ix. p. 50).

Glauber's salt is a constituent of many mineral waters, and occurs in small quantity in the blood and other animal fluids. It occurs, under the name of *Thénardite*, near Madrid, in the form of anhydrous octahedra deposited at the bottom of some saline lakes; and is found combined with sulphate of lime, as *Glauberite* ($\text{NaO}, \text{CaO}, 2\text{SO}_3$), in the valley of the Ebro.

The anhydrous salt is prepared in enormous quantity from common salt and oil of vitriol, with the view of being afterwards converted into carbonate of soda. See **SODA**.

For medical use a purer form is required. The salt which remains after the distillation of hydrochloric acid—this salt being sulphate of soda contaminated with free sulphuric acid—is dissolved in water, to which is added powdered white marble (carbonate of lime), to neutralise the free acid; and to precipitate it as an insoluble sulphate; the solution is boiled down till a pellicle appears, is strained, and set aside to crystallise.

It is used as a common purgative, and is especially applicable in fevers and inflammatory affections, when it is necessary to evacuate the bowels without increasing or exciting febrile disturbance. The usual dose is from half an ounce to an ounce; but if it is previously dried, so as to expel the water of crystallisation, it becomes doubly efficient as a purgative. It is now much less frequently used in domestic medicine than formerly, having given place to milder aperients.

GLAUBER'S SPIRIT OF NITRE is one of the old terms for nitric acid.

GLAUCHAU, a thriving manufacturing town of the kingdom of Saxony, is picturesquely situated on the right bank of the river Mulde, 8 miles north-north-east of Zwickau. Owing to the unevenness of its site, it is irregularly built; but its appearance is striking. It is the second in rank among the manufacturing towns of Saxony. Here and in the neighbourhood, the weaving of every kind of goods flourishes; there are also important dye-works, print-works, iron-foundries, and machine factories. Pop. 14,360.

GLAUCOMA (Gr. *glaukos*, sea-green), an opacity of the vitreous humour of the eye, characterised by a bluish tint seen from without, and the absence of the peculiar characters of Cataract (q. v.), which, in some respects, it resembles as regards the gradual obscuration of vision. It is an almost incurable disease.

GLAUCONIE, a French term introduced by M. Brogniart as the name of several strata of different ages. The *Glaucanie Crayeuse* and *Sablense* are equivalent to the Upper and Lower Greensand, while the *Glaucanie Grossier* is an Eocene deposit contemporaneous with the Bracklesham beds.

GLAU'OUS, a genus of molluscs, referred to the class *Gasteropoda*, but having no distinct respiratory organs. The body is long, slender, gelatinous, furnished with three pair of digitated finlike appendages, which were formerly supposed to be gills. The mouth has horny jaws, adapted for preying on other small marine animals. These small molluscs—about an inch and three-quarters long, of a blue colour, and extremely delicate and beautiful—inhabit the tropical parts of the Atlantic Ocean, and float inertly with irregular movements of the slender branches of their fins on the surface of the water.

Glaucus Atlanticus.

GLAUX, a genus of plants of the natural order *Primulaceæ*, having a 5-lobed calyx, no corolla, and a 5-valved capsule with about five seeds. *G. maritima*, sometimes called **SEA MILKWORT** and **BLACK SALTWORT**, is one of the most common plants of our sea-coasts, growing in almost every muddy situation. It is a small plant, with branching stems, often procumbent, and small fleshy leaves. It makes a good pickle.

GLAZE. See **POTTERY**.

GLEANNING. In conformity with the positive command contained in the Mosaic law, to leave the gleanings of the harvest to the poor and to the stranger (Levit. xix. 9, and xxiii. 22), there has been almost everywhere a popular feeling to the effect that the farmer was not entitled to prevent the poor from gathering what the reaper had left behind. In England, the custom of gleaning had very nearly passed into a legal right, for there is an extra-judicial dictum of Lord Hale, in which he says that those who enter a field for this purpose are not guilty of trespass, and Blackstone (iii. 12) seems disposed to adopt his opinion; but the question has since been twice tried, and decided in the negative in the Court of Common Pleas, the court finding it to be a practice incompatible with the exclusive enjoyment of property, and productive of vagrancy and many mischievous consequences, 1 H. Bl. Rep. 51. It is still, however, the custom all over England to allow the poor to glean, at least after the harvest is carried. The privilege is one which, both from motives of humanity and of economy, ought certainly to be continued within proper limits, because it not only adds to the comfort and wellbeing of the poor, but by preserving from waste a portion of the fruits of the earth, and

Sea Milkwort (Glaux maritima):
a, a flower.

by employing children and infirm persons whose labour would not be available for any other purpose, it diminishes the expenditure for the support of the indigent, which already presses so heavily on the industrious portion of the community. It is a privilege, however, which is apt to be abused by able-bodied persons, who, by rising early in the morning, and going into fields from which the crop has only been partially carried, contrive to carry off grain to a greater value than the wages which they could have earned by honest harvest-work. With a view to checking this abuse, farmers in various districts have established rules for regulating the practice of gleaning. Some curious statistics on the subject of gleaning were published in the *Journal of the Statistical Society of London*. In Bohn's *Political Dictionary*, under the head 'Gleaning,' a statement is made shewing that the total gleanings of 388 families was £423, 12s., and the average for each family £1, 1s. 10d., which was one-fifth of the average harvest-wages of each of the same number of families.

In Scotland, it has been more than once decided that the poor possess no right to glean, at common law, and that the farmer may exclude them from his fields (*Hutch. Justice of the Peace*, ii. 47; *Dunlop's Paroch. Law*, 223).

GLEBE (Lat. *gleba*, a clod or lump of earth), the land possessed as part of an ecclesiastical benefice, or from which the revenues of the benefice arise. The assignment of glebe-lands was formerly held to be of such absolute necessity, that without them no church could be regularly consecrated. In England, the word manse includes both the parsonage-house and the glebe, whereas in Scotland it is applied exclusively to the house. The fee-simple of the glebe is held by the law of England to be in *abeyance*, from the French *bayer*, to expect—that is to say, it is only 'in the remembrance, expectation, and intendment of the law;' but after induction, the freehold of the glebe is in the parson, and he possesses most of the powers of a proprietor, with the exception of the power of alienation. Previous to the Reformation, the clergy possessed certain powers of alienation at common law; and if a bishop, with the assent of his chapter, or an abbot, with the assent of his convent, or the like, alienated glebe-lands, the deed would not have been void, because the fee-simple was in the holder of the benefice for the time being; but by 1 Eliz. c. 19, and 13 Eliz. c. 10, all gifts, grants, feoffments, conveyances, or other estates, shall be utterly void and of none effect, notwithstanding any consent or confirmation whatever. Neither could the incumbent exchange the lands or any portion of them without the authority of an act of parliament. This restriction was done away by 55 Geo. III. c. 147, for enabling spiritual persons to exchange parsonage or glebe houses or glebe-lands for others of greater value or more conveniently situated for their residence and occupation. By 5 and 6 Vict. c. 54, it is now provided that the commissioners appointed to carry into effect the commutation of tithes shall have power to ascertain and define the boundaries of the glebe-lands of any benefice, and also power, with consent of the ordinary and patron, to exchange the glebe-lands for other lands within the same or any adjoining parish, or otherwise conveniently situated. The subsequent act 17 and 18 Vict. c. 84 moreover provides that the incumbent of any benefice entitled to glebe, shall, with such consents as are specified in the act, be entitled to annex such glebe or other lands by deed to any church or chapel within the parish, district, or place wherein such glebe or land is situate. In addition to his glebe-lands, the rector or vicar is also seized in the edifice of

the church itself (see **CHURCH**). It was long ago provided (28 Henry VIII. c. 11, s. 6), that if an incumbent died after having manured and sown the glebe-lands, he might make his testament of the profits of the corn; but if his successor be inducted before the severance thereof from the ground, he shall have the tithe; for although the executor represent the person of the testator, yet he cannot represent him as parson.

Glebe, in Scotland.—In Scotland, as in England, a glebe forms, as a general rule, a portion of every ecclesiastical benefice of the Established Church, and is thus an addition to the stipend, and sometimes a very important one. Ministers in royal burghs, however, cannot claim glebes, unless in the case in which there is a landward district attached to the parish. Even then, if there are two ministers, only the first can claim a glebe. Where parishes are disjoined, or separated into two portions, moreover, it does not necessarily follow that the portion erected into a new parish shall contain a glebe. By 5 Geo. IV. c. 72, provision is made for payment of compensation out of the public revenue, in lieu of manse and glebe, to ministers whose stipends do not exceed £200. If there are arable lands, the glebe must not be less than four acres. If there is no arable land, the minister is entitled to sixteen *soums* of grass adjacent to the church. A *soum* is as much as will pasture ten sheep or one cow, so that the actual extent varies with the richness of the soil and consequent quality of the pasture. The presbytery possesses the power of designing glebes, the heritor from whose property the glebe is designed having recourse against the other heritors of the parish. By 1572, c. 48, it is enacted that the glebe shall not be alienated by the incumbent. As the act limits its prohibition to such alienation as may be detrimental to the successor of the incumbent, it has been doubted whether the latter might not feu. The court, however, has been very unwilling to sanction this proceeding; and from the fact that land tends steadily to increase, whereas money diminishes in value, it seems of very doubtful propriety even where the arrangement is very advantageous at the time. When the church is changed, or transported, as it is called, to a new site, the court will authorise the sale or excambion of the glebe, but such excambions must be sanctioned by the presbytery. Where minerals are found on the glebe, they are worked under the superintendence of the heritors and presbytery for the behoof of the incumbent. Trees growing on the glebe are thought to belong to him. See **TEIND COURT**.

GLEE, the English name of a vocal composition for three or more voices, and in one or more movements. The style of music of the glee is peculiar to England, and quite different from the part-songs of Germany.

GLEET. See **GONORRHEEA**.

GLEIG, the REV. GEORGE ROBERT, M.A., a popular author and divine, son of the Right Rev. George Gleig, LL.D., Bishop of Brechin, and Primus of the Scots Episcopal Church, was born at Stirling, in Scotland, in 1796. In 1812, while a student at the university of Oxford, he joined as a volunteer a regiment then marching through that city on its way to Lisbon. Soon obtaining a commission in the 85th Regiment of light infantry, he served in the Peninsula. During the American war in 1812–1814, he was engaged in the campaign of Washington, at the capture of which city, in August 1814, he was severely wounded. In 1821 he published an account of the *Campaigns of Washington and New Orleans*, 8vo. At the close of the war, he

retired on half-pay. He now completed his studies at Oxford, entered into holy orders, and in 1822 was presented by the Archbishop of Canterbury to the living of Ivy Church, Kent. In 1825, he published *The Subaltern*, a novel founded on his experience in the Peninsular War. In 1844, he was appointed chaplain of Chelsea Hospital, and in 1846, Chaplain-general of the Forces. Having devised a scheme for the education of soldiers, he was appointed Inspector-general of Military Schools. In 1848, he was made a prebendary of St Paul's Cathedral, London. G. has written a great variety of biographical, historical, and religious books. The most interesting and important of all his works is his *Life of the Great Duke of Wellington* (1859, new ed. 1862).

GLEIWITZ, a town of Prussia, in the south-east of the province of Silesia, is pleasantly situated on the Klodnitz, a small affluent of the Oder, 43 miles south-east of Oppeln. It contains three churches, a synagogue, and a Catholic gymnasium, and is noted for its royal foundries, iron-works, leather manufactures, spinning and weaving. Pop. 9787.

GLENCOE, a valley well known not only for the terrible massacre through which it has become historically famous, but also for the wildness and sublimity of its scenery, is situated in the north of Argyleshire, near the border of Inverness, at Loch Leven. It is about eight miles in length, and is divided into an upper and lower valley by a gentle ridge. It is traversed by a mountain-stream called the Cona, and its scarred sides shew the beds of numerous mountain-torrents. After entering the glen, the traveller looks in vain for any token of social life or of civilisation.—**MASSACRE OF GLENCOE.** The principal circumstances of this famous tragedy are briefly as follows. The state of the Highlands in the year which followed the parliamentary session of 1690 was such as to give the government much anxiety. The civil war which had recently been flaming there continued still to smoulder, and at length it was determined, at court, to employ £12,000 or £15,000 in quieting and reconciling the refractory clans. The Edinburgh authorities issued a proclamation exhorting the clans to submit to William and Mary, and offering pardon to every rebel who would swear on or before the 31st December 1691 to live peaceably under the government of their majesties, and threatening to treat all who refused to do so as enemies and traitors. All the chiefs submitted before the 31st December except MacIain, the chief of the Macdonalds of Glencoe, whose submission, from unforeseen causes, was delayed till the 6th of January. The magistrate before whom he took the oath of allegiance transmitted a certificate to the Council at Edinburgh, explaining the circumstances of the case. That certificate was never laid before the Council, but was suppressed by an intrigue, directed (it is supposed) by the Master of Stair (Sir John Dalrymple, afterwards second Viscount and Earl of Stair), on whom, undoubtedly, rests the chief blame of this odious transaction. The enemies of MacIain now hurried on their plans for his destruction. The Master of Stair obtained the king's signature to an order directed to the commander of the forces in Scotland, and which runs thus: 'As for MacIain of Glencoe and that tribe, if they can be well distinguished from the other Highlanders, it will be proper, for the vindication of public justice, to extirpate that set of thieves.' Accordingly, on the 1st of February, 120 soldiers—most of them Campbells, who had a personal spite against the Macdonalds—led by a Captain Campbell and a Lieutenant Lindsay, marched to Glencoe.

They had been warned by Stair to do nothing by halves; they were exhorted to be 'secret and sudden,' and they obeyed their instructions. Arrived in the glen, they told the Glencoe men that they were come as friends, and only wanted quarters. For twelve days the soldiers lived in the glen. Captain Campbell, or Glenlyon as he was called from the name of his estate, while visiting daily at the chief's house, employed himself in observing carefully what avenues and passes there were by means of which the Macdonalds might escape, and reporting the result of his observations to Lieutenant-colonel Hamilton, who was approaching with troops to secure the passes. The morning of the 13th of February was fixed for the slaughter, and on the night of the 12th, Glenlyon was supping and playing at cards with those whom he meant to assassinate before dawn. At five in the morning the murderous work began. When the day dawned, 38 corpses, among which were several of women, and more dreadful still, the hand of an infant that had been struck off in the murderous tumult, were lying in or around the village in their blood. But the massacre comprehended only a small portion of the tribe, for Hamilton not having come up in time, the passes were open, and about 150 men, and probably as many women, escaped, but only in many cases to perish from cold or hunger among the snows in the high mountain-gorges. When Hamilton did arrive, he was disappointed in finding the work so imperfectly done, and seizing an old Highlander, whom, being above seventy, the other butchers had agreed to let live, murdered him in cold blood. The huts of the village were then set on fire, and the troops departed, driving away with them all the flocks and herds of the glen.

The question as to the share of King William in the guilt of this transaction has been discussed with no little warmth on both sides. Lord Macaulay pleads, in vindication of the king's conduct, that the certificate detailing the submission of MacIain had been suppressed; that he knew the Macdonalds only as a rebellious clan, who had rejected his conciliatory offers; and that, in signing the order for their extirpation, he certainly never intended them to be murdered in their sleep, but merely that their organisation as a predatory gang should be broken up.—The scene of the massacre is visited annually by tourists, who are accommodated with conveyances in connection with Hutcheson's steam-vessels from Glasgow.

GLENDOWER, or **GLENDWR**, **OWEN**, a Welsh chief, who was one of the most active and formidable enemies of Henry IV. of England. He was descended from Llewelyn, the last Prince of Wales, and followed the fortunes of Richard II. to the close, when, in 1399, Henry of Bolingbroke usurped the crown, and assumed the title of King Henry IV. Taking advantage of G.'s known attachment to the dethroned monarch, Lord Grey of Ruthyn seized part of his land. G.'s suit for its restitution was dismissed by parliament, and then Lord Grey seized the rest of his land. Revenge and despair, conspiring with a martial disposition, and the encouraging prophecies of the Welsh bards, drove him to take up arms, and provided him with followers. In 1400, he commenced operations by seizing the estates of Lord Grey. The king ordered his subjugation, and granted his estates to his brother the Earl of Somerset. G.'s forces were inferior in number to those of his adversaries. He was sometimes victorious, chiefly through surprises, ambushes, and the like, but sometimes defeated, and forced to retire to the hills, where his positions and rude fortifications could not be approached. In 1402, he drew Lord Grey into an ambush, and took him prisoner. This

nobleman was ransomed on paying 10,000 marks, and the king, out of jealousy of the Earl of March (a boy of ten, the true heir to the crown), or some similar cause, allowed him to pay his own ransom. Immediately on his release, Lord Grey married a daughter of G.; and it would appear that Sir Edmund Mortimer, the uncle of the Earl of March, married another, having been captured also a little later by G., in a battle in which 1100 of Mortimer's followers were left dead upon the field. Treason seems to have been falsely imputed to Mortimer as the cause of his defeat; but Henry IV.'s suspicions and G.'s kindness soon made the treason sufficiently real, for Mortimer induced his sister's husband, Earl Percy (Hotspur), to conspire with him and G. (now proclaimed Prince of Wales) against the government. Percy led with him into the same enterprise the Scotch Earl Douglas, whom he had just taken prisoner at Homildon Hill. This coalition against royalty ended in the battle of Shrewsbury, in July 1403, in which the fall of Hotspur and the late arrival of G. gave the victory to the king and his forces. In June of the following year, G. entered into a treaty with Charles VI. of France against the English. Little came of it, for next year, G. sustained severe reverses, and was driven to wander among the caves of the mountains with a handful of adherents. Another two or three years saw his fortunes somewhat in the ascendant, and they fluctuated in the ordinary levels of the petty warfare of a bold barbarous chief, with mountains to escape to against the advance of superior civilised numbers, which he could no more resist on the plains than they could destroy him among the mountains. He died a natural death in the house of one of his daughters, on the 20th September 1415, aged about 65, having spent the last fifteen years of his life in constant turmoil and warfare. His successes shew that he had about the highest talents of his class, and he had their faults also. The popular idea of him is to be found in Shakspeare's *King Henry IV.* From the first, he has been a kind of mythical hero, and the lapse of centuries does not clear up the exact facts of his history. His rebellions were the expiring fires of the independence of Wales, which the English kings had been treading out for nearly a century and a half.

GLENELG is a shallow river of considerable length, which rises in the south-west part of Victoria, and which, after crossing the boundary into South Australia, enters the Southern Ocean between Cape Northumberland on the west, and Cape Bridgewater on the east. Its mouth is about lat. 38° S., and long. 141° E.

GLENLIVET, a vale or district in the south-west of Banffshire, extends along the course of the Livet, a small feeder of the Avon, at the distance of about 21 miles south-west from Huntly. It contains iron ore and lead, and has long been famous for its finely flavoured whisky. Here a battle took place between the Earl of Argyle and the Earl of Huntly in 1594, resulting in the defeat of the former.

GLENROY, PARALLEL ROADS OF. The Roy is a small stream in the district of Lochaber, Inverness-shire, having a course of about 15 miles, and falling into the Spean at Inverroy, opposite to Ben Chlunaig, the eastern spur of Ben Nevis. The steep narrow valley through which the Roy runs is remarkable for having its faces marked with three shelves, which appear as lines running right round it; they are everywhere perfectly horizontal and parallel to each other, and in each case the line on one side of the glen corresponds exactly in elevation to that on the other. The granitic and metamorphic

rocks, of which the mountains are composed, are covered with a greater or less thickness of angular fragments and earth, and an examination of the shelves shews that they are worn out of this soft alluvial coating. The accompanying sketch explains their structure. They almost invariably form a gentle slope from the hillside, and are from 3 to 30 feet wide. The protrusion of the rocky body of the mountain, and the furrows of mountain torrents, break their continuity, but with these exceptions, one or more of them may be traced along the whole valley. The highest, which is 1139½ feet above the sea-level, is easily followed from the watershed between the Roy and the Spey (which

Glenroy.

is at the same elevation), along both sides of the valley, as far down as the point at which the valley narrows above Glen Glaster. The second shelf is 80 feet lower, runs parallel with the first all round the head of the valley, and is continued further down until it includes Glen Glaster. The third line is 212 feet lower than the second; it may be traced along both sides of Glenroy, and round the mouth of the glen into the valley of the Spean, whose sides, at the same elevation of 847 feet, is marked from within 3 miles of the river Lochy up nearly as far as Loch Laggan. What is very curious, the elevation of the highest shelf corresponds with that of the watershed at the head of Glenroy (where it opens towards the valley of the Spey); the second corresponds with the watershed at the head of Glen Glaster (where it opens towards Glen Spean); and the third is at the same level with the valley of passage between Spean and Spey at Muckall. There is yet a higher shelf in the neighbouring Glen Gluoy, at an elevation of 1159½ feet above the sea.

Many attempts have been made to explain the origin of these remarkable shelves. Their forming somewhat level roads around the valley, originated the popular notion, that they were made for the convenience of the heroes whose exploits are sung by Ossian. Playfair, in 1816, supposed they were aqueducts for artificial irrigation. Macculloch believed them to be the shore-lines of fresh-water lakes, which gradually washed away their barriers, remaining for a longer space at the height of the various shelves. Sir T. D. Lauder embraced and illustrated the same view. Darwin considered that the glens were former arms of the sea, and that the shelves indicated periods of rest in the elevation of the land. Agassiz and Buckland returned to the opinion of Macculloch, but finding no indication or remains of any solid land barrier, they referred the lake to the glacial period, and held that two large

glaciers came down from Ben Nevis, the one near the centre of the mountain, and the other along the basin of Loch Treig, and that these dammed up the water in the included portion of Glen Spean and in Glenroy. In a paper subsequently published by Mr David Milne, the lacustrine theory was reverted to, with several new and plausible illustrations. The reader is referred to a work of Mr R. Chambers (*Ancient Sea-margins*, 1848) for a full account of this remarkable district. He enumerates no less than 21 terraces or shelves, in addition to the four prominent ones already described, at heights varying from 325 to 1495 feet. And uniting all these into a regular series, he endeavours to shew that they are owing to the recession of the sea from these glens, and that the intensity of the shore-markings depended upon the angle at which the hill met the water, the nature of the surface of the hill, and the quietness of the water.

GLENTILT, a deep, narrow valley in the north of Perthshire, extends in a south-west direction from the Grampians on the north to Strathgarry on the south, and is 15 miles in length. Through the bottom of the glen the Tilt rushes with great impetuosity, and the mountains on each side are scored with innumerable torrents. Its upper half is enclosed among mountains of from 3350 to 3589 feet high, and its left boundary is mainly formed by the huge Ben-y-Gloe, which rises from a broad base, and has many summits, the highest being 3725 feet above sea-level. The lower half is less wild. This glen is classic ground to the geologist. Two elaborate accounts of its geological phenomena have been published—one by Dr McCulloch, to be found in the *Transactions of the Geological Society*; and the other by Lord Webb Seymour, which appears in the *Transactions of the Royal Society of Edinburgh*.

GLIDDON, GEORGE R., American Egyptologist, antiquary, and ethnologist, was born in 1807 in Grand Cairo, Egypt, where his father, John Gliddon, was for many years United States consul. He resided for 32 years in the valley of the Nile and in the Levant, and had extraordinary opportunities for pursuing those scientific researches to which he appears to have devoted a large portion of his life. He filled, for several years, the post of United States consul at Cairo.

About the year 1840, Mr G. visited London, Paris, and his own country, to which he had been so entirely a stranger. In the United States, he gave lectures in all the principal cities from Boston and New York to Mobile and New Orleans on Egyptian and other Oriental antiquities. His earliest work, *Ancient Egypt, her Monuments, Hieroglyphics, History, and Archaeology*, &c., was so successful, that 18,000 copies were sold in America alone in three years. It has passed through many editions. He published also, at about the same period, an *Appeal to the Antiquaries of Europe on the Destruction of the Monuments of Egypt*; *Discourses on Egyptian Archaeology*; *A Memoir on the Cotton of Egypt*; and *Otia Egyptiaca*.

In the course of his travels in the United States, Mr G. formed acquaintances with men of science who were interested in his Egyptian researches, and who, in turn, interested him in a broader range of ethnological investigations. Conspicuous among these were Dr Morton of Philadelphia, distinguished for his craniological investigations; Dr Nott of Mobile, Alabama; Professor Agassiz, the naturalist; and others. He wished now to avail himself of the advantages of European museums and libraries, but had not the necessary means. He found, however, a generous friend in Mr Richard K. Haight of New York, who imported costly works from Europe,

not then to be found in America, and also furnished him with money for a visit to London, Paris, and Berlin. The results of his studies are to be found in two quarto volumes, published by Mr G., with the co-operation of Dr Nott, and several other savants, both European and American. In 1854 was published *Types of Mankind, or Ethnological Researches based upon the Ancient Monuments, Paintings, Sculptures, and Crania of Races*, &c., by J. C. Nott, M.D., of Mobile, Alabama, and George R. Gliddon; and containing papers by Dr Morton, Professor Agassiz, and Drs Usher and Pattison of Philadelphia. In 1857 was published, also in a handsome quarto volume, *Indigenous Races of the Earth, or New Chapters of Ethnological Inquiry*, including Monographs by M. Alfred Maury, Librarian of the French Institute; Francis Pulasky, a learned Hungarian; and Professor Meigs of Philadelphia. This work bears also the joint names of Nott and G.; and Mrs Gliddon, an accomplished artist, gave her assistance in drawing upon the wood the engravings with which it is profusely illustrated. Just as this work was published, Mr G. died at Panama, Isthmus of Darien, whither he had gone to pursue his ethnological researches.

Mr G. was an enthusiast, not only in his investigations, but in the advocacy of his theories or convictions, and is unsparing in his criticisms of his opponents. He has laboured to prove the great antiquity and diversity of origin of the human races. His works have been severely criticised and condemned by those who hold to the popular chronology and the unity of the race. The materials he has brought together are valuable and suggestive; but his treatment of them can scarcely be considered satisfactory; and he is not free from the suspicion of a bias in favour of the enslavement of certain of those whom he considered inferior races.

GLIRES (Lat. plural of *glis*, a dormouse), in the Linnæan system of zoology, an order of Mammalia almost exactly corresponding to the *Rodentia* (q. v.) of Cuvier and other more recent naturalists.

GLOBE-FISH. See DRODOR.

GLOBE-FLOWER (*Trollius*), a genus of plants of the natural order *Ranunculaceæ*, having a calyx of coloured (yellow) sepals, in number five or some multiple of five, the petals small and linear. There are several species, natives of the colder parts of the northern hemisphere. The common G., the LUCKEN GOWAN of the Scotch (*T. Europæus*), is the only species found in Britain, and chiefly in the northern parts, where it is one of the finest ornaments of moist grounds and river-banks in somewhat elevated districts. It is sometimes cultivated in flower-gardens. The name G. is derived from the appearance which the flower presents, the sepals being curved so that it forms almost a perfect yellow globe or ball. It is a native of all the northern parts of Europe, and also of the Alps.

GLOBES. A globe is a round or spherical body (see SPHERE), and in the singular number the word is

Globe-Flower (*Trollius Europæus*).

often used to signify the earth, as in the phrase, 'the terraqueous globe;' but by 'globes,' or 'the globes,' we usually mean a pair of artificial globes used as a part of school-room apparatus. These globes are hollow spheres of card-board, coated with a composition of whiting, glue, and oil, upon which paper bearing certain delineations is laid. On one of the pair—the *celestial* globe—are represented the stars, so placed that, to an eye supposed to observe them from the centre of the globe, their relative position and distance correspond to those actually observed; while on the *terrestrial* globe, the distribution of land and water, the divisions and subdivisions of the former, together with a few of the most important places, are laid down in the positions corresponding to those which they actually occupy on the surface of the earth.

The usual mode of manufacture is as follows: A ball of wood or iron is used as a matrix, and a layer of damped paper is carefully and closely placed upon this, without paste, and other layers are successively pasted over the first one; ordinary card-board is thus produced, but instead of being flat, as usual, it forms a spherical shell. When sufficiently thick, this is cut into two hemispheres, the section being made in the line of the intended equator. The hemispheres are then taken off the matrix, and again glued together on an axis, and the whiting composition laid on, the outside of which is smoothed and finished to shape in a lathe. The workman has to lay on this composition so as to balance the globe, in order that it may rest at whatever point it is turned. The smooth surface is now marked with the lines of latitude and longitude, and is covered with the paper on which the required geographical or astronomical delineations are engraved. In order to adapt the plane surface of the paper to the curvature of the sphere, it is printed in pieces, small circles for the Arctic and Antarctic regions, and the rest in lens-shaped gores, varying from 20° to 30° of longitude, and meeting these circles which are pasted first. Great care is required in laying on these curved pieces, so that their edges shall meet exactly without overlapping. The surface is then coloured, and strongly varnished, and mounted in its frame and stand.

Globes of india-rubber and gutta-percha have also been made, others of thin paper, to be inflated and suspended in a school-room. Betts's paper-globes fold up when not in use. Embossed globes shew, in exaggerated relief, the elevations and depressions of the earth's surface. Compound globes including the celestial and terrestrial, are made with an outer glass sphere for the celestial, and orrery mechanism to shew the varying relative positions of the sun and moon, &c.

As school-room apparatus, globes are used for the purpose of illustrating the form and motion of the earth, the position and apparent motion of the fixed stars, and for the mechanical solution of a number of problems in geography and practical astronomy. For this purpose, each globe is suspended in a brass ring of somewhat greater diameter, by means of two pins exactly opposite to each other—these pins forming the extremities of the axis round which it revolves, or the north and south poles. This brass circle is then let into a horizontal ring of wood, supported on a stand, as represented in the art. *ARMILLARY SPHERE*; in which the lines drawn on the surface of globes are also explained. The globes in common use in schools are 12 inches in diameter; those to be found in private libraries are more frequently 18 inches.

The problems to which the globes are applied are such as: To find when a star rises, sets, or comes

to the meridian on a given day at a given place. The mode of solution will be found in any school-book on the subject. The answers obtained in this way to such questions are only very rough approximations, and are in themselves of little or no value. But 'the use of the globes,' as it is called, serves the purpose of making evident to the senses how many of the appearances connected with the motions of the earth and the heavenly bodies are caused, and enabling the nature of the problems connected with these appearances to be clearly conceived. It is only by trigonometrical calculation that the accurate solutions can be obtained.

GLO'BULINE, or **CRYSTALLINE**, is one of the proteine bodies or albuminates. In association with hæmatine, as hæmato-globulin, it is the main ingredient of the blood globules; and it occurs, mixed with albumen, in the cells of the crystalline lens of the eye, forming, according to Simon, from 10 to 14 per cent. of the dry lens. Hence its two names. In most of its relations it resembles albumen, but differs from that substance in being precipitated both from acid and alkaline solutions by exact neutralisation, and in being completely thrown down from its solutions by carbonic acid gas.

GLO'BUS HYSTERICUS, or **Ball in the Throat**, the name applied to a peculiar sensation described under **HYSTERIA**.

GLO'CKNER, or **GROSS GLOCKNER**, the highest peak of the Noric Alps, is situated on the boundary between Tyrol, Carinthia, and Upper Austria, and is 12,431 feet in height.

GLO'GAU, or **GROSS-GLOGAU**, a town and important fortress of Prussia, in the province of Silesia, is situated on the left bank of the Oder, 35 miles north-north-west of Liegnitz. It is surrounded by walls, and is otherwise fortified; and is connected by a wooden bridge with a strongly fortified island in the Oder. It has a beautiful castle, two gymnasiums, one Catholic, and the other Protestant; and numerous religious and educational institutions. On the island in the Oder is a cathedral dating from 1120, and containing a Madonna, the masterpiece of Cranach, Sen. Manufactures of woollens, printed calicoes, hosiery, tobacco, paper, and sugar, and some trade and commerce are carried on. Pop. 16,656, including a garrison of 3653 men.

GLO'GGNITZ, a small town of Austria in the province of Lower Austria, is situated on the Schwarza, at the northern base of the Semmering Alp, a branch of the Noric chain, 45 miles south-south-west from Vienna. Pop. 1200. It is a station on the Vienna and Trieste Railway, and stands at the northern extremity of that portion of it known as the *Semmeringbahn*, or railway of the Semmering. This portion of railway is perhaps the most extraordinary work of its kind in Europe. It sweeps up the steep rocky face of the mountain in many curves, and descends its southern slope, after having passed through 15 tunnels and crossed as many bridges. It extends from G. on the north to Mürzzuschlag on the south, a distance of 25 miles. The greatest elevation is reached 23½ miles south of G., where the line is 2872 feet above sea-level, and 1504 feet above its height at Gloggnitz. To this point the line rises in gradients of from 1 in 40 to 1 in 100; the average rate of ascent, however, is 1 in 82. At its greatest elevation, the line pierces the Semmering in a tunnel 4633 feet long. Quick trains take 1 hour and 42 minutes to traverse these 25 miles; slow trains require 2 hours 33 minutes. The *Semmeringbahn* was constructed for the Austrian government by

Carlo Chega, an eminent engineer, between the years 1848 and 1853.

GLOMMEN, or **STOR-ELV** (i. e., *great river*), the largest river in Norway, rises from Lake Aursund, at the town of Røros, in lat. about 62° 40' N., and long. 11° 16' E. Its source is 2419 feet above sea-level, and its course is interrupted by frequent water-falls, the last of which, with a descent of 60 feet, is called the Sarpenfos or Sarp-fos, and occurs at about 10 miles from the mouth of the river. Large boats can ascend to the Sarpenfos. The G. flows first in a south-west direction for about 50 miles, then bends toward the south-east, and pursues that direction until it passes the fortress of Kongsvinger, after which it again turns south-west, and empties itself into the Skager Rack at Frederikstadt, after a course of about 400 miles. Its most important affluents are the Rena on the left, and the Vorma on the right.

GLORIA, a hymn in the Roman Catholic Church service, beginning with the words, 'Gloria in excelsis Deo.' Its place in the mass is after the 'Introitus,' except on the penitential days in Advent and during Lent, when it is omitted. It is founded on the 2d chapter of St Luke, 14th verse. It has been so long in use that it is not known by whom it was introduced into the service in its present form. It is also called 'The Great Doxology,' to distinguish it from the 'Gloria patri filio et spiritui,' which is sung at the end of the Psalms and antiphonal hymns.

GLORIOSA, a genus of plants of the natural order *Liliaceae*, having a perianth of 6 elongated and reflexed segments, a 3-lobed stigma, a 3-celled superior germin, and globose seeds. The best known species, *G. superba*, a native of India, is a herbaceous perennial with a weak stem, 6—10 inches high, alternate leaves terminating in tendrils, and very beautiful flowers, finely coloured with red and yellow.

GLORIOUS VIRGIN, or **ST MARY THE GLORIOUS**, an order of knighthood in Venice, founded by Bartholomew of Vicenza, and approved by Pope Urban IV. in 1262. This institution was ecclesiastical as well as military, and its objects were the protection of widows and orphans, and the furtherance of the peace of Italy. The badge was a purple cross between certain stars, and the costume a white surcoat on a russet cloak.

An order of knighthood of St Mary the Glorious also existed in Rome in the 17th c., whose purpose was the suppression of the Barbary corsairs who infested the Mediterranean.

GLOSS (in Biblical criticism), Gr. *glossa* (tongue, or language), an explanation of purely verbal difficulties of the text, to the exclusion of those which arise from doctrinal, historical, ritual, or ceremonial sources. The words which are commonly the subject of these glossarial explanations are reducible to five classes: (1) foreign words; (2) provincialisms or dialects; (3) obsolete words; (4) technical words; and (5) words used by the author in some abnormal or exceptional signification. From an early period, these verbal difficulties were the object of attention, and the writers who devoted themselves to the elucidation were called *glossatores*, and their works *glossaria*. The principal Greek glossatores are Hesychius, Zonaras, Suidas, Phavorinus. Most of the Rabbinical writers have done the same work for the Hebrew text; so that it would be difficult to name any in particular as Hebrew glossatores. The chief glossatores of the Latin Vulgate are the celebrated Walafrid Strabo in the 9th c., and Anselm of Laon in the 12th, for the Latin Vulgate.

In Roman and canon law, the practice of introducing glosses was of early origin, and probably was an imitation of the biblical glosses. Among jurists, the gloss was not purely verbal, but regarded the true interpretation of the law, and in some cases it was held to be of equal authority with the text itself. From the position which it occupied in the MS., being generally written between the lines of the text and on the margin, it was called *glossa interlinearis*. The gloss of the Roman law is written in very pure Latinity, that of the canon law in the Latinity of the medieval schools.

GLOSSITIS (Gr. *glossa*, the tongue), inflammation of the tongue. The disease in its most acute form is rare; it is sometimes due to injury, or to scald; in other cases, to the action of mercury on the system. The tongue becomes enormously swollen, and one of the chief dangers of the attack is suffocation from swelling of the parts about the hyoid bone, and closure thereby of the glottis (see **LARYNX**). The only really effective treatment is to make pretty deep incisions into the inflamed part, keeping in view that the resulting wound is likely to be much less than appears at the time; for the enlargement of the organ has stretched the mucous membrane, and infiltrated all the textures with fluid, while the vessels also are distended with blood. A straight bistoury should be boldly plunged into the upper surface, and several incisions made lengthways sufficiently deep to evacuate the confined fluids. A good deal of blood will usually follow, but if care has been taken not to injure the lingual artery or its branches (see **TONGUE**), there is no real danger from this cause. In places at a distance from medical advice, this operation might require to be performed by unskilled hands, and with a penknife or any other cutting instrument at hand; care should be taken in this case to make the incisions on the upper surface, and not too far from the middle line.

GLOTTIS. See **LARYNX**.

GLOUCESTER, a city and county in itself, the chief town of the county of the same name, an inland port, cathedral town, watering-place, and the seat of some important manufactures, situated on the left bank of the river Severn, distant west-north-west from London 107 miles by road, and 114 by rail, and from Bristol 36 miles north-north-east. G. is clean and well built, with four principal streets, of convenient width, meeting at right angles in the centre of the city. The docks are spacious, and communicate with the open part of the Severn, below Sharpness Point, by means of a ship-canal 17 miles in length, while the wharfs, about 1000 feet in length, are directly connected with the several railways. The foreign trade is principally with the Black and Baltic seas, Canada, the West Indies, and France; the foreign import returns for 1861 give 458 vessels, and an aggregate tonnage of 130,947; exports, 98; tonnage, 20,676. Coasting-trade inwards, 994 vessels, of 40,584 tons; outwards, 3561; tonnage, 141,040. G. is connected by the Midland Railway with the north, by the Bristol and Gloucester Railway with the west and south, by the Great Western with London and the east, and by the South Wales Railway with the principality. Besides affording a market for the produce of the surrounding districts, G. imports corn, timber, wines, and spirits in considerable quantities, has a large export trade in iron and steel goods, coal, soap, malt, and potter-ware, railway-fittings, agricultural implements, bells, pins, chemicals, and hempen goods.

The principal building in G. is the cathedral, cruciform in structure, and presenting beautiful

GLOUCESTER—GLOVES.

examples of several different eras of ecclesiastical architecture, 427 feet in length, and 154 in width; the height of the central tower, its greatest external ornament, is 223 feet; the cloisters also, of great beauty, form a large square. Formerly the church of a Benedictine abbey, it was converted into a cathedral in 1541. There are, besides the cathedral, 12 churches of the Establishment; 2 Wesleyan and 2 Independent chapels; 1 Catholic, Baptist, Methodist, Friends, Unitarian, and Lady Huntingdon's Chapel, a grammar-school, many excellent public and private schools, a neat theatre, assembly rooms, town-hall, jail, and lunatic asylum. G. returns two members to parliament. Pop. (1851), 17,572; (1861), 16,320. It is noted as one of the three cities (Worcester and Hereford being the other two) at which the musical festivals of the three choirs are alternately held. The history of G. is traceable to a very remote antiquity; it was the *Caer Glow* of the Britons, *Colonia Glevum* of the Romans, and an important town in *Mercia* under the Saxons, by whom it was called *Glean-Ceaster*—whence its present name. Here the celebrated single combat between Edmund Ironsides and Canute is said to have taken place. G. was repeatedly visited by William I., afforded a refuge and support to Queen Matilda in her contest with Stephen, saw Henry III. crowned, and parliaments held under Richard II. and Henry IV., and sided successfully with the parliament in the civil war against Charles I. Robert of Gloucester, the metrical historian; Miles Smith, biblical translator; the Poet Taylor; and R. Raikes, the founder of Sunday schools, were natives of Gloucester.

GLOUCESTER, a town, seaport, and fishing-station, of North America, in the state of Massachusetts, is situated on the south side of Cape Ann, about 28 miles north-east of Boston. It is handsomely built and finely situated, and commands extensive sea-views. Its 'harbour,' one of the best on the coast, is roomy, safe, easily accessible, and deep enough to admit vessels of the largest size. G. is said to be the first fishing-town in the United States. The fishing vessels in 1859 numbered 357, and were manned by 3890 fishermen. In 1855 the mackerel fishery realised 388,809 dollars, or over £80,000; and the cod fishery 293,860 dollars, or over £60,000. The town has, besides, extensive manufactories of anchors, cables, sails, oil, soap and candles, and provisions. G., which is connected with Boston by a branch-railroad, has recently become a favourite summer resort for sea-bathing. Pop. (1855), 8935; (1859), estimated at 12,000.

GLOUCESTERSHIRE, a county of England, lying around the lower course of the Severn and the estuary of that river, is bounded on the W. by Monmouth and Hereford, on the N. by Worcester and Warwickshire, on the E. by Oxfordshire, and on the S. by Somerset and Wilts. Area, 805,102 acres; pop. (1851) 458,805; (1861) 455,502. The shape of the county resembles a parallelogram, and though its outline is still somewhat irregular, especially in the north, it is much less so than formerly, as by act 7 and 8 Vict. c. 61, outlying portions of the county of G. were annexed to the counties in which they were respectively situated; and, in like manner, detached pieces of land belonging to other counties, but situated in G., were declared portions of that county. There are three distinct districts in this county, the natural features of each being different. These are the Hill, the Vale, and the Forest districts; the first formed by the Cotswold or Cotswold Hills (q.v.), the second, comprising the vales of Gloucester and Berkeley, by the rich and low meadow-lands lying

along the banks of the Severn; and the third consisting of the land west of the Severn, which is occupied chiefly by the Forest of Dean. The county is watered principally by the Severn, the Wye, the Upper and Lower Avon, and the Thames or Isis, which receives all the streams on the east of the Cotswold Hills. The soil is thin on the hills, but produces good pasturage for sheep, while the lower tracts abound in excellent grass and arable lands. The vales of G. are remarkable for the early maturity of their agricultural produce. The famous Double and Single Glo'ster cheese is produced at Berkeley, in the vale of that name, and is sold throughout the kingdom. The Forest of Dean, 20,000 acres of which are still crown property, is highly picturesque in appearance, and contains many apple-orchards, from which a favourite cider is made. A lord-warden, who is constable of the castle of St Briavel's, with six deputy-wardens, and other officers, superintend the government of the forest. In this county, numerous and important manufactures are carried on; of these, the manufacture of woollen cloth, of the better qualities, is the chief; hats, felt, stockings, pins, cheese-cloths and other linens are also produced in considerable quantities. The county sends four members to the House of Commons.

G., previous to the Roman invasion, was inhabited by a tribe called the Dobuni; and after that event, the county, or the greater part of it, was included in the province named *Flavia Caesariensis*. From the earliest of the Danish invasions down to the battle of Tewkesbury, in 1471, and to the civil wars between the crown and parliament, G. has been the scene of many and disastrous encounters. It contains numerous Roman relics in camps, roads, coins, fragments of statuary and pottery, tessellated pavements, &c. There are also many traces of British, Saxon, and Danish works in the county.

GLOVER, RICHARD, was born in London in 1712, and was educated at Cheam, in Surrey. He was a merchant in his native city, and in 1760, became member of parliament for Weymouth. His first poem, to the memory of Sir Isaac Newton, was written in his 16th year. His chief poem, entitled *Leonidas*, was published in 1737, and passed through several editions. A continuation of it, the *Atheniad*, was published in 1787. These poems are in blank verse, and of prodigious extent. Although not deficient in a certain majesty and elevation of tone, they are in the main turgid and heavy, and are now almost entirely forgotten. He wrote several tragedies, which did not meet with success. His most popular poem, *Hosier's Ghost*, written on the taking of Carthage from the Spaniards, was published in 1739. He died in 1785; and in 1813, appeared a diary, or part of a diary written by him.

GLOVES. Gloves are made of various materials, such as silk, wool, linen, cotton, fur, and various kinds of leather. The latter material is the most abundantly used, and the mode of making it up is the most characteristic of this branch of manufacture. We need scarcely inform the reader that the term 'kid' is a mere technicality, as the quantity annually consumed of leather bearing this name is largely in excess of what could be supplied from the skins of all the young goats that are annually slaughtered. It is chiefly made from lamb's skin. A few of the finest gloves are made from real kid skins, obtained from those countries where goats' milk and flesh are articles of food. Dogskin, buckskin, and doe-skin gloves are made chiefly from sheepskin; some of the thickest kinds of leather gloves are made from calf-skin. The

GLOVES—GLOWWORM.

leather in all cases undergoes a much lighter dressing than when used for boots and shoes.

Worcester is the chief seat of the English leather glove-manufacture; gloves are also made at Ludlow, Leominster, and Yeovil, besides Woodstock, where a peculiar and superior doeskin glove is made bearing the name of the town. Limerick and the neighbourhood has long been celebrated for gloves.

The French, however, still excel us in this branch of manufacture. Up to 1825, the importation of French gloves was prohibited, and the competition consequent upon the removal of this prohibition had the usual effect of producing a rapid improvement in the English manufacture. Very cheap and good gloves are made at Naples; and they are much in request on the continent.

After the leather has been properly prepared, it is cut into pieces of the required size, then folded over somewhat unequally, as the back should be larger than the front. Three cuts are then made through the doubled piece to produce the four fingers; an oblong hole is cut at the bending of the fold for the insertion of the thumb-piece: the cutting of this of the exact shape and size requires considerable skill. The first and fourth fingers are completed by gussets or strips sewed only on their inner sides, while the second and third fingers require gussets on each side to complete them. Besides these, small pieces of a diamond shape are sewed in at the base of the fingers towards the palm of the hand. The stitching together of these pieces requires much care, as the junction must be made as closely as possible to the edge of each piece, and yet with sufficient hold to keep the stitches from cutting through the material. A kind of vice or clamp, with minute teeth to regulate the stitches, is sometimes used for this purpose; and sewing-machines are applied as far as practicable, especially for the ornamental or embroidery stitching on the backs. The putting in of the thumb-piece requires special skill and management. Badly made gloves commonly give way at this part. The superiority of the French and the best English gloves depends chiefly upon the adaptation of their shape to the structure of the hand by giving additional size where the flexure of the hand requires it. The best woollen, thread, and silk gloves are made as above by cutting and sewing together, but commoner gloves are made to a great extent by knitting and weaving in like manner to stockings.

Glove-dyeing.—The dye is lightly washed over the stretched glove, a second and third coat being given after the first is dry. When this is thoroughly dried, the superfluous colour is rubbed off, and the surface smoothed by rubbing with a polished stick or piece of ivory. The surface is then sponged over with the white of egg.

Glove-cleaning.—Oil of turpentine or camphine was the material chiefly used for cleaning kid gloves, but of late this has been to a great extent superseded by Benzole (q. v.) or benzine, which is abundantly obtained in sufficient purity for this purpose by the careful rectification of coal-naphtha. The chief advantages of this latter material is, that it is more volatile, and its odour less persistent than that of ordinary turpentine, or even of the best rectified camphine which has been much exposed to the atmosphere. The mode of using either of these is to stretch the gloves over a wooden hand of suitable size, and then sponge them with the fluid, removing the first or dirty portion with a second wash of clean fluid. By collecting the washings separately, and allowing them to stand till the dirt settles, the same turpentine or benzole may be used over and over again.

An inodorous composition may be made by dissolving one part of soap-shavings in two parts of rain or distilled water, using heat to aid the solution. This is improved by adding to it a small quantity of liquor ammonia and any ordinary perfume. It should be applied to the glove stretched on the stock by rubbing with a piece of flannel always in one direction.

Doeskin and wash-leather gloves, when not very dirty, may be cleaned dry by rubbing them when stretched on a stock with a mixture of finely powdered fuller's-earth and alum, then sweeping off this powder with a brush, and dusting with dry bran and whiting. If the gloves are very dirty, they should be washed with the soap solution, then rubbed with pipe-clay mixed with yellow ochre or amber (according to the shade required), made into a paste with ale or beer, then carefully dried and dusted to remove the superfluous powder.

Glove Powder, for cleaning gloves, is made by carefully drying Castile soap, and then pounding it in a mortar; or of pipe-clay coloured with yellow ochre or Irish slate, or it may be made of a mixture of pipe-clay and powdered soap.

GLOVES (in Law). It is an old custom in England on a maiden assize—i. e., an assize on which there is no offender to be tried—for the sheriff to present the judge with a pair of white gloves. The clerk of assize and the judges' officers have money given to them on the same occasion, which is called *glove silver*. The custom of presenting white gloves to the judges on a maiden circuit is also observed in Scotland.

GLOWWORM, the name given to the wingless females of certain coleopterous insects of the family *Lampyridæ*, remarkable for the luminosity of some of the last segments of the abdomen. The insects of the family *Lampyridæ* have five joints in all the tarsi, the antennæ toothed, the elytra (wing-covers)—at least of the males—covering the whole abdomen,

Glowworm (*Lampyris noctiluca*):
1, male; 2, female.

the whole body soft and the elytra flexible, the females often destitute both of wings and elytra, the thorax projecting over and almost concealing the head. When seized, they place their feet and antennæ close to the body, many of them also curving the abdomen downward, and simulate death. The COMMON G. (*Lampyris noctiluca*) is abundant in some parts of England, and rare in the south of Scotland. The antennæ are short. The male has very large eyes. The female, which is larger than the male, is fully half an inch in length, of a blackish colour, the legs dusky red, and the thorax and abdomen margined with that colour. The female is perfectly destitute both of wings and elytra. The habits of the insect are nocturnal. The male emits a faint light, the female a soft but strong light, of which the use is supposed to be to attract and guide the male. The female G. is generally to be found, during the summer months, among grass, or on mossy banks. There is reason to think that the G. has the power of displaying and extinguishing its light at pleasure, so that it may not be

unnecessarily exposed to enemies; but if the luminous portion of the abdomen be removed, it retains its luminosity for some time. If placed in hydrogen gas, it sometimes detonates. The luminous matter is capable of being mixed with water, and warm water increases its brilliancy. Two spots on the last segment of the abdomen are more luminous than any other part, and a constant motion of this segment seems to be connected with the emission of the light. The two segments next to this are each surrounded by a band brighter than the rest of the segment. The larva of the *G.* is very similar to the perfect female insect, but is very faintly luminous. It is very voracious, attacking and devouring snails, whereas the perfect insect eats little, and is supposed to prefer the tender leaves of plants.—Several species of *G.* are found in the warmer parts of Europe, and in other parts of the world. The luminosity of the males of the genus *Lampyrus*, and of other winged insects of the family *Lampyridæ*, has obtained for them the name of Fireflies (q. v.).

GLUCHOV, a town in the south-west of Russia, in the government of Tchernigov, and 112 miles in direct line east-north-east of the town of that name. It is surrounded by earthen walls, contains eight churches, has manufactures of cloth, and some trade in grain and brandy. In the vicinity, porcelain clay is obtained, and is sent north to the imperial manufactory at St Petersburg. Pop. 8556.

GLUCINA (more correctly, **GLYCINA**, from Gr. *glykys*, sweet), derives its name from its salts having a sweetish taste. It was discovered by Vauquelin, in 1797, in the emerald, and has since been found in cymophane, chrysoberyl, phenokite, the gadolinites, leucophane, and belvine; but in consequence of the great difficulty of preparing it, its properties and combinations have not been much studied. Berzelius regarded it as the sesquioxide of Glucinum (q. v.), in which case its formula would be Gl_2O_3 , but it is now generally believed to be a protoxide, GlO . For the mode of extracting it from the emerald or other mineral containing it, we must refer to Debray's *Memoir on Glucinum and its Compounds* (a translation of which is given in the eighth volume of the *Quarterly Journal of the Chemical Society*), or to any of the larger works on chemistry. Glucina is a white, loosely coherent powder, without taste or smell. It is infusible, but volatilises at a very high temperature.

Amongst the salts of glucina that have been studied by Debray and others, we may mention the sulphates of glucina, and of glucina and potash; the carbonates of glucina, and of glucina and potash; and the oxalates of glucina, of glucina and potash, and of glucina and ammonia. They are colourless, and much resemble those of alumina.

The mineral *phenakite* is a pure silicate of glucina. The *beryl*, of which the *emerald* is a variety, is a double silicate of glucina and alumina. The mineral *eucrase* is also a double silicate of the same earths; while the *chrysoberyl* is an aluminate of glucina, coloured with peroxide of iron.

GLUCINUM (symbol, Gl), known also as **GLYCINUM**, **GLYCUM**, and **BERYLLIUM**, is a metal whose atomic weight is 4.65 (as deduced by Awdejew from the analysis of sulphate of glucina), and whose specific gravity is 2.1. It is white, malleable, and fusible below the melting-point of silver. It does not burn in air, oxygen, or sulphur, but in the first two substances it becomes covered with a thin coat of oxide. It combines readily with chlorine, iodine, and silicon. Even when heated so redness, it does not decompose water. It dissolves readily in hydrochloric and sulphuric

acids, and in a solution of potash, but is insoluble in ammonia, and only slightly acted on by nitric acid. It forms one oxide, **GLUCINA**.

From the researches of Debray, it follows that *G.* should be placed side by side with aluminium. These bodies are intermediate between the precious and the ordinary metals, and both of them are characterised by the following properties: They are permanent in the air at high as well as at low temperatures; do not decompose water, even when they are at a white heat; are not attacked by sulphur, sulphuretted hydrogen, or the alkaline sulphides; are not attacked by strong nitric acid at ordinary temperatures, and only slowly, even with the aid of heat; but dissolve readily in dilute sulphuric and hydrochloric acids.

G. was first obtained from glucina by Wöhler, in 1827, who procured it by decomposing the chloride of *G.*, which is obtained by evaporating a solution of glucina in hydrochloric acid. Debray has since (1854) obtained it much more abundantly by applying a similar mode of proceeding to that employed by Sainte Claire Deville for the reduction of aluminium.

GLUCK, JOHANN CHRISTOPH VON, a German musical composer, who may be considered the father of the modern opera, was born, July 2, 1714, at Weissenwangen, in the Upper Palatinate. He learned the rudiments of music in one of the common schools of Prague, and as a wandering musician went to Vienna, where he found opportunity to master the rules of counterpoint and harmony. In 1738, he went to Italy, to complete his musical education, and found a worthy master in San-Martini. After four years of study he wrote his first opera, *Artaxerxes*, which was performed at Milan, 1741. This was followed by *Ipermestra* and *Demetrio*, given at Venice, 1742, and several others in the two following years, produced at Milan and Turin. Having achieved a high reputation, *G.* was invited to London, where his *Fall of the Giants* was represented in 1745. He found a formidable rival in Handel, whose genius he honoured, and he derived great advantages from the friendship of Dr Arne, the English composer, and his lady, an excellent singer. It was here that he began to develop the full force of that lyric genius which was destined soon to create a new order of musical composition; but the outbreak of the Rebellion in Scotland closed the opera, the singers and musicians being mostly Roman Catholics, and *G.* returned to Vienna. In 1754, he was called to Rome, where he wrote *La Clemenza di Tito*, *Antigono*, and several others. But he did not rise to that high style of art which distinguished his later works until he found at Florence, in Ranieri di Calzabigi, a poet whose dramas were worthy of his music. He then composed the three operas, *Alceste*, *Paride e Elena*, and *Orfeo*, which became the foundation of an imperishable fame. He made music the interpreter of poetry, giving to it the fullest expression. His simple, noble, and grand style filled Europe with admiration. He changed no less the action of the stage than the music. Before him all was artificial and insipid. He made everything natural and effective. At Paris, 1777, he became the rival of the great Italian composer Picini, and the city was divided into two rival factions of the Gluckists and the Picinists. He conquered with his *Iphigénie en Tauride*, 1779. Picini, who had composed an opera on the same subject, would not allow his to be performed after listening to that of his rival. His great triumph was followed by several successful works, and he enjoyed the highest patronage and prosperity. He died of apoplexy, November 25, 1787. Burney has characterised him

GLÜCKSTADT—GLUCOSE.

in a single phrase, when he calls him 'the Michael Angelo of music.'

GLÜCKSTADT, a town of Denmark, capital of the duchy of Holstein, is situated on the right bank of the Elbe, on the Kremper Marsh, 32 miles below Hamburg. It is a pretty town, regularly built, and intersected by canals. The chief buildings are the high school, the school of navigation, the house of correction, the workhouse for Slesvig and Holstein, and the theatre. It has a safe port capable of containing 200 ships, and furnished with wharfs. The water with which the town is supplied requires to be gathered into cisterns and artificially purified. Weaving is carried on here to some extent; but trade, navigation, and whale-fishing employ the inhabitants chiefly. G. was founded in 1620 by Christian IV. of Denmark, fortified, and endowed with various commercial privileges. During the Thirty Years' War, it successfully withstood three sieges; its fortifications were demolished in 1815. It has been a free port since 1830. Pop. 6145.

GLUCOSE (or, more correctly, GLYCOSE), known also as GRAPE SUGAR, STARCH SUGAR, and DIABETIC SUGAR ($C_6H_{12}O_6 + 2aq$), seldom occurs in distinct, well-formed crystals, but may be obtained in warty concretions, which, when examined under the microscope, are found to consist of minute rhombic tablets. It never, however, crystallises readily. It is less sweet than ordinary (cane) sugar, is soluble in water and in dilute alcohol, and its solutions rotate the plane of polarisation from left to right, this effect on a ray of polarised light being more marked than with cane sugar. At 212° , it fuses, and loses its water of crystallisation, and at a higher temperature (about 400°) it undergoes change, loses the elements of water, and becomes converted into Caramel ($C_{12}H_{20}O_8$), a brown substance, which is neither sweet nor capable of undergoing fermentation, but which is readily soluble in water, and is much used by cooks and confectioners as a colouring matter. At a still higher temperature, it becomes entirely decomposed into carbonic oxide, carbonic acid, light carburetted hydrogen (C_2H_4), acetic acid, aldehyde, furfural, and a very bitter substance, to which the name *Assamar* has been applied.

With bases, glucose forms various definite but unstable compounds, which have been termed *saccharates*, a term which ought to have been restricted to the salts of saccharic acid. On heating an alkaline solution of glucose, decomposition ensues, and a dark-brown uncrystallisable substance is formed, which possesses acid properties, and is known as *melassic acid*. This reaction is sometimes employed for the detection of glucose, and is known as Moore's test.

Glucose has a strong reducing power, and upon this property several of its tests are based. It reduces the oxide of copper, even without the aid of heat, in alkaline solutions to the state of the yellow suboxide, and this reaction is apparent when only 0.0001 of glucose is present in the fluid. This is known as Trommer's test, and Fehling's mode of determining glucose quantitatively is based on the same reaction. In consequence of this reducing power, sugar is sometimes employed in the solution of the silver salts used for the silvering of mirrors.

Glucose readily undergoes fermentation. On mixing a solution of it, kept at a moderate temperature, with yeast, each equivalent of it breaks up into two equivalents of alcohol, and four equivalents of carbonic acid, or—

Under the influence of other exciters of fermentation,

as, for instance, putrid animal membranes, or other nitrogenous substances, glucose becomes converted first into lactic acid, and subsequently into butyric acid. These reactions are exhibited in the two following formulæ:

Under certain conditions, which are not accurately known, solutions of glucose undergo a change which is termed *viscous fermentation*. The sugar becomes converted into a viscous or ropy substance, while lactic acid and mannite ($C_6H_{12}O_{11}$) are formed. This kind of fermentation sometimes occurs in light-bodied white wines. Water is probably decomposed, and its hydrogen unites with a portion of the glucose to form mannite.

Glucose is a constituent of the juice of grapes, plums, cherries, figs, and many other sweet fruits, and may often be observed in a crystalline form on raisins, dried figs, &c. It likewise occurs in honey. In the animal kingdom, it is found sometimes as a normal and sometimes a pathological constituent of various fluids and tissues. Thus, it occurs normally in the contents of the small intestine, and in the chyle after the use of amylaceous and saccharine food, in the blood of the hepatic veins (see LIVER), in the tissue of the liver, in both the yolk and white of birds' eggs, in the urinary secretion in minute quantity (according to Brücke, Bence Jones, and others), &c.; while in the disease known as diabetes, it exists in large quantity in the urinary secretion, and may be detected in nearly all the fluids of the body. By injuring a certain part of the medulla oblongata (the part of the spinal cord contained within the cavity of the cranium), an artificial diabetes can be produced.

The mode of formation of glucose, whether in the laboratory or in the organisms of plants and animals, requires some notice. It can be obtained chemically from starch and from dextrine by boiling them with dilute sulphuric acid, or by the action of Diastase (q. v.), and from cellulose and gum, and from most of the varieties of sugar, by treatment with dilute acids. In the liver, it is formed from the Glycogen (q. v.) which occurs in that organ, under the influence of a ferment which has been chemically separated from the hepatic tissue, but with the nature of which we are not acquainted; while in the rest of the organism it is formed from the starch which is taken with the food, the starch undergoing this transformation under the influence of ptyaline (a ferment occurring in the saliva), pancreatine (a ferment occurring in the pancreatic juice), and an unknown but corresponding ferment existing in the intestinal fluid.

The simplest method of preparing pure glucose is by treating honey with cold rectified spirit, which extracts the uncrystallisable sugar; the residue is dissolved in water, and the solution is decolorised with animal charcoal, and allowed to crystallise.

It is manufactured on a large scale, especially on the continent, from starch. A mixture of starch and water at a temperature of about 130° is made to flow gradually into a vat containing water acidulated with 1 per cent. of sulphuric acid, and kept at the boiling-point. In about half an hour, the starch is converted into sugar. The liquid is drawn off, and the sulphuric acid is neutralised by the gradual addition of chalk, till there is no longer any effervescence. The sulphate of lime is deposited, and the clear aqueous solution, after being concentrated by evaporation, is set aside to crystallise. The molasses is drained off, and the sugar is dried at a gentle heat in a current of air. 'The

GLUCOSURIA—GLUTTON.

chief use,' says Dr Muspratt, in his *Chemistry Applied to Arts and Manufactures*, 'to which glucose is applied on the continent, is for the manufacture of beer and a coarse kind of alcohol, which is said to be extensively converted into French brandy by the addition of oil of raisins, colouring matter, &c.'

As all alcoholic drinks (ales, wines, and spirits) are obtained from fluids containing this variety of sugar as the essential constituent, and as their quality mainly depends upon the amount of sugar that is present, it is very important to have some ready means of determining its amount. A similar determination is also of great value in reference to the urinary secretion in diabetes, as it is mainly by ascertaining whether the daily amount of excreted glucose is diminishing or increasing that we can trace the favourable or unfavourable progress of the case.

Without entering into details, we may mention that there are three different modes of determining the amount of glucose in a fluid: the first is by determining the specific gravity; the second is the optical test, which is based upon the fact (already noticed), that solutions of sugar (whether grape, cane, or milk sugar) exert right-handed rotation upon a ray of polarised light, the angle of rotation being proportional to the percentage of sugar. Soleil's apparatus for determining sugar in this way is described in the article *POLARISING APPARATUS*. The third is by chemical means, of which the most important are Barreswil's method and the fermentation test. Barreswil's method is based upon the property which glucose possesses of throwing down suboxide of copper from alkaline solutions of oxide of copper.

In employing the products of the fermentation of glucose as a means of determining its quantity, we take a given quantity of the saccharine fluid, add a little well-washed yeast, and collect the carbonic acid that is evolved over mercury. Roughly speaking, a cubic inch of carbonic acid corresponds to a grain of sugar.

Much information upon the different tests for glucose, and upon their relative degrees of delicacy, will be found in a paper recently published by Dr Bence Jones in the *Quarterly Journal of the Chemical Society*, 1861, vol. xiv. p. 22.

GLUCOSURIA, a modern name for Diabetes Mellitus (see *DIABETES*), and indicative of its characteristic symptom, the presence of sugar in the urine.

GLUE. See *GELATINE*.

GLUE, MARINE, a cementing composition used in ship-building, and for other purposes, where the materials are exposed to the influence of wet. It consists of india-rubber cut very small—one part digested at a gentle heat in a closed vessel with twelve parts of mineral naphtha until it is dissolved, then twenty parts of powdered shell-lac are added, and the digestion continued until it also is dissolved. During both stages of the process, the mixture must be stirred or shaken occasionally. It requires to be liquefied by heat before using, and must be quickly applied, as it very soon hardens. It is particularly valuable in consequence of its power to cement not only wood, but glass and metals, and also to resist the action of moisture. Its employment, however, requires some care and skill.

GLUME, in Botany, a small bract or scale, in the axil of which there grows either a single flower destitute of perianth, as in the *Cyperaceæ*, and in some of the Grasses; or, as in others of the Grasses, a spikelet composed of a number of flowers (*Florets*). The Grasses (*Gramineæ*) and *Cyperaceæ* are some-

times conjoined under the appellation *Glumaceous Plants*.

GLUTEN is one of the most important constituents of the varieties of corn used as food. It is obtained by mixing flour with water, and thus forming a paste or dough. This paste is placed in a bag of fine linen, and kneaded in water, which must be repeatedly changed, till it ceases to assume a milky appearance. A gray, tenacious, viscid, tasteless substance, having the appearance of bird-lime, is left in the bag. This substance consists mainly of gluten, mixed with traces of bran starch and of oily matter. The gluten thus obtained from wheat and from rye is far more tenacious than that which is obtained from the other cereals, and it is the great tenacity of this constituent that especially fits these flours for conversion into bread. It is found by analysis, that the proportion of gluten contained in wheat grown in Algeria and other hot countries is considerably higher than in wheat grown in England, or still colder countries; and the hard, thin-skinned wheats contain more of this ingredient than the softer varieties of the grain. It forms about 16 per cent. of Algerian wheat; about 15 per cent. of wheat from the Black Sea; and nearly 14 per cent. of South Carolina wheat; about 10·7 per cent. of English wheat; 9·8 per cent. of Canadian wheat; and less than 9 per cent. of Danzig wheat.

Gluten in a moist state rapidly putrefies, the mass acquiring the smell of decaying cheese; but when dry, it forms a hard, brownish, horny-looking mass, that does not very readily decompose. On treating gluten with hot alcohol, we find that it resolves itself into at least two distinct substances, one of which is soluble, and the other insoluble in that fluid.

The insoluble portion is regarded by Liebig as vegetable fibrine. It is a gray, tough, elastic substance, insoluble in water or in ether, but readily soluble in dilute alkalies, from which it is precipitated by neutralisation with acetic acid. It is also soluble in very dilute hydrochloric acid, from which it is thrown down by the neutral salts.

The soluble portion is in part precipitated from the alcohol on cooling, in the form of flakes, which have the composition and properties of caseine; while a third substance remains in solution, giving to the alcohol a sirupy consistence. It separates, on the addition of water, as a white substance resembling albumen. It is usually known as *gliadin*, but some chemists—Dumas and Cahours, and others—have termed it *glutin*, a name which is objectionable on the ground that it is already engaged for the chief form of gelatine. All these constituents of gluten contain carbon, hydrogen, nitrogen, oxygen, and sulphur, in much the same proportion as the animal albuminates or proteine bodies, and they all doubtless belong to the flesh-forming group of foods.

The action of gluten in the manufacture of bread is probably a double one; it induces, by constant action, an alteration of the starch, and subsequent fermentation, while by its tenacity it prevents the escape of carbonic acid gas.

GLUTTON (*Gulo*), a genus of quadrupeds usually referred to the bear family (*Ursidae*), but which constitutes an interesting connecting-link between that and the weasel family (*Mustelidae*), agreeing more nearly with the latter in dentition, although approaching to the former in the plantigrade character. There are three false molars in the upper, and four in the lower jaw, anterior to the carnivorous tooth, which is large and sharp. The body is long, the legs are short, the feet have each five

GLYCERIA—GLYCERINE

deeply divided toes, terminated by long curved claws. The tail is rather short, a fold beneath the tail supplies the place of the glandular pouch of the badgers; but when hard pressed by enemies, the gluttons emit a peculiar fluid of a strong musky odour. Their

Glutton (*Gulo arcticus*).

habits are nocturnal. The species commonly called GLUTTON, and also WOLVERENE (*G. arcticus*), is a native of the northern parts of Europe, Asia, and America. It is more common in the arctic regions than towards the southern limits of its distribution, which are about the forests of Courland, in Europe, and the mountainous parts of Massachusetts, in America. It is about two feet six inches or two feet nine inches in length, from the tip of the nose to the root of the tail; the tail about seven or eight inches long, both body and tail covered with long hair, under which the body is covered with a rich thick fur. The general colour of the long hair is brown, sometimes approaching to black, lighter bands passing from the neck along the flanks, and meeting at the tail. The short fur is chestnut brown. The muzzle is black. A light-brown band runs across the forehead from ear to ear. The fur of the G. is sometimes of considerable value, and is used for muffs, cloaks, &c., but varies not a little in glossiness and other qualities. The most extraordinary stories were at one time credited concerning the ferocity, voracity, and cunning of this animal, and have not altogether disappeared from books of natural history. It is very capable of domestication, and even in a wild state exhibits no remarkable ferocity; nor is there any reason to believe that it leaps from trees on deer, or pursues any of those artful methods of procuring food which were once ascribed to it. It often preys on animals which it has not itself killed. The smaller quadrupeds are its principal food, and it devours young foxes in great numbers. Its speed is not great, but it excels in strength and perseverance. The traps set for the smaller kinds of animals in the fur countries of North America are very often robbed by the wolverene, and it has been known to remove a great pile of wood, in order to get at provisions which had been hidden under it.—Closely allied to the G. are the Grison and the Ratel. Bone-caverns and some of the newest deposits exhibit remains of more than one species of Glutton.

GLYCERIA. See MANNA GRASS.

GLYCERINE ($C_3H_5O_3$), known also as hydrated oxide of lipyl, or hydrated oxide of glyceryl, was discovered by Scheele in 1779, who obtained it in the preparation of lead-plaster, and named it 'the sweet principle of oils.' It is a colourless, viscid, neutral, uncrystallisable, inodorous fluid, of a sweet

taste, is soluble in water and alcohol in all proportions, but is nearly insoluble in ether. Its specific gravity at 59° is, according to Miller and most authorities, 1.28, but Gorup-Besana makes it as high as 1.97. At 40°, it becomes gummy and almost solid; at 212°, it is slightly volatile; but if distilled alone, the greater part of it becomes decomposed; it may, however, be distilled without alteration in a current of superheated steam which has been raised to a temperature of between 500° and 600°. By this means, Mr Wilson* has succeeded in separating heated fats into hydrated glycerine, and the acids with which it was previously in combination; the glycerine is thus obtained in a high state of concentration as a colourless, syrupy liquid, which can be thus prepared in unlimited quantity.

Glycerine forms soluble compounds with baryta, strontia, and lime; and it dissolves oxide of lead and numerous salts. Berthollet has found that glycerine, like Mannite (q. v.), is convertible into a true fermentable sugar, when digested with certain animal tissues.

Glycerine occurs ready formed in a few fats (as, for example, old palm-oil), and, according to Pasteur, is contained in all fermented liquors, and especially in wine, its quantity amounting to three per cent. of the fermented sugar. It is a product of the saponification of the various fats, although it does not exist as glycerine, but rather as a substance having the composition represented by the formula $C_3H_5O_3$. According to Berthollet's view, glycerine is a triatomic alcohol, and may be represented by the formula $C_3H_5O_3.3HO$; and in the animal and in many vegetable fats, the three atoms of water are replaced by three atoms of the anhydrous fatty acid. Thus—

In the saponification of these fats—that is to say, when they are treated with potash, soda, or oxide of lead, or under the influence of heated steam—the fatty acid separates from $C_3H_5O_3$, which assimilates three atoms of water, and becomes glycerine.

We have already referred to the best mode (Wilson's process) of obtaining glycerine on a large scale; the usual method of obtaining it on a small scale is from olive oil, which we saponify by treating it with an equal weight of oxide of lead (litharge), which is mixed with water, and added to the oil, with which it is boiled till the saponification is complete. The glycerine is dissolved by the water, and is easily separated from the insoluble lead-plaster (a mixture of oleate and palmitate of lead). Any traces of lead are removed by sulphuretted hydrogen, and the water is then expelled *in vacuo*, or over the water-bath. The former is preferable, as in the open air the glycerine becomes brown.

The uses of glycerine are numerous. In medicine, it is employed as a local application in diseases of the skin and of the ear; and it is used internally as a solvent for many drugs. It is a valuable preservative fluid for small and delicate anatomical preparations, and it has been applied to the preservation of meat. It has been added to the water in gas-meters, with the view of preventing it from

* The chemical superintendent at the works of Price's Patent Candle Company.

freezing in winter, or from evaporating too rapidly in summer. It is used in the manufacture of copying-ink, and is of general application wherever a lubricating agent is required.

Many interesting researches have been carried on during the last few years regarding the true chemical nature and the artificial production of glycerine; they are, however, for the most part of a too purely chemical nature to be made intelligible to the general reader. We will merely remark that, like the alcohols in general, to which class glycerine is now assigned, it forms several classes or series of derivatives, the most important of which are its combinations with acids, forming *glycerides*, or compound ethers of glycerine, which are analogous in their composition to the various fats and oils. Berthollet has succeeded in forming these bodies synthetically, and has thus not only reproduced several of the natural fats, but has obtained a large class of similar bodies which were not previously known.

Treated with sulphuric acid, glycerine yields *sulphoglyceric acid* ($C_3H_5O_4, 2SO_3$), and treated with phosphoric acid, it yields *phosphoglyceric acid* ($C_3H_5O_6, PO_4, HO$), a substance which occurs normally, in combination with soda and ammonia, in the brain and in the yolk of egg.

GLYCINE, GLYCOCINE, GLYCOCOLL, or SUGAR OF GELATINE ($C_2H_5NO_2$), occurs in colourless, transparent, rhombic prisms, which have a sweet taste, and are devoid of odour. It is very soluble in water, the solution having no effect on vegetable colours, but is insoluble in alcohol and in ether. Glycine combines both with acids (as hydrochloric, nitric, sulphuric, and oxalic acid) and with metallic oxides, and the compounds in both cases are soluble and crystallisable; they are, however, of no great importance.

It is usually described as an animal base, but some chemists regard it as belonging to the class of bodies termed amido-acids, and as being amido-acetic acid; that is to say, acetic acid ($C_2H_3O_2$) in which one of the atoms of hydrogen is replaced by one atom of amidogen (NH_2). According to this view, its formula should be written $C_2H_4(NH_2)O_2$. Glycine is a product of various processes of decomposition of animal matters.

GLYCOGEN ($C_6H_{10}O_5, HO$, according to the analysis of Pelouze) is a substance which in its properties seems intermediate between starch and dextrine. In contact with saliva, pancreatic juice, diastase, or with the blood or parenchyma of the liver, it is converted into glycose, and hence its name of glycogen. It occurs only in the cells of the liver, where it exists as an amorphous matter; but in the early stage of fetal life, before the liver begins to discharge its functions, instead of being found in that organ, it exists in special cells in the foetal structures known as the placenta and the amnion, and in the muscles, horny tissues, &c. In severe forms of disease, and especially in febrile affections, it seems to be temporarily absent from the liver. Its uses in the animal economy are noticed in the article LIVER.

GLYCOL is the type of a new class of artificial compounds, whose existence was inferred, and afterwards discovered, a few years ago, by Wurtz. In their chemical relation and properties, they form an intermediate series between the monobasic or monatomic alcohols, of which common alcohol is the type on the one hand, and the class of bodies of which ordinary glycerine is the type, on the other. The name of glycol, formed from the first syllable of glycerine and the last of alcohol, has been given to express this relation. According to the Theory of

Types which is now commonly accepted (see TYPE, THEORY OF CHEMICAL), the glycols are termed diatomic alcohols, ordinary alcohol being a monatomic, and glycerine being a triatomic alcohol.

Ordinary glycol is formed from ethylene (C_2H_4), and hence it may be called ethyl-glycol, to distinguish it from propyl-glycol, which is formed from propylene (C_3H_6), from butyl-glycol, which is formed from butylene (C_4H_8), or from amyl-glycol, which is formed from amylene (C_5H_{10}).

Glycol is a colourless, slightly viscid fluid, with a sweet taste, and its composition is expressed by the formula $C_2H_4O_2$. For further information on this class of bodies, we must refer to any of the recent works on organic chemistry, or to a lecture on the *Histoire générale des Glycols*, delivered by Wurtz before the Chemical Society of Paris, and published in the *Leçons de Chimie professées en 1860*, par MM. Pasteur, Cahours, Wurtz, &c., 1861.

GLYCO'SMIS, a genus of plants of the natural order *Aurantiaceae*, trees, natives of the East Indies and the Mascarene Islands. The fruit of *G. citrifolia*, an East Indian species, is delicious.

GMELIN, LEOPOLD, a celebrated chemist, was born at Göttingen, in August 1788, and died at Heidelberg, in April 1853. His father was professor of natural history and botany at Tübingen, and afterwards of chemistry at Göttingen; and for at least four generations members of the Gmelin family have distinguished themselves in chemistry and natural history. After taking his degree in medicine, he spent several years at Tübingen, Vienna, and Naples, in the study of chemistry and mineralogy; and in the autumn of 1813, he began his public career as a teacher of chemistry at Heidelberg, where, twelve months afterwards, he was appointed extraordinary professor of chemistry. He discharged the duties of his office with unremitting zeal until 1843, when he had an attack of paralysis; and in 1850, in consequence of a second attack, he was obliged to resign his professorial office. He published numerous contributions to chemistry and mineralogy in Schweigger's *Journal*, Poggendorff's *Annalen*, Liebig's *Annalen*, and in Leonhard's *Jahrbuch*, between the years 1815 and 1844. In 1820, he undertook, in conjunction with Tiedemann, a series of experiments on digestion; and in 1826, these philosophers published their celebrated work on this subject, under the title of *Die Verdauung nach Versuchen*, in two volumes. 'But' (Report of the Council of the Chemical Society for 1854) 'the greatest service which Gmelin rendered to science—a service in which he surpassed all his predecessors and all his contemporaries—consists in this: that he collected and arranged in order all the facts that have been discovered in connection with chemistry. His *Handbuch der Chemie* stands alone. Other writers on chemistry have indeed arranged large quantities of materials in systematic order, but for completeness and fidelity of collation, and consecutiveness of arrangement, Gmelin's *Handbook* is unrivalled.' The first edition of this great work appeared in 1817—1819, and included, in two vols. of moderate size, the whole extent of chemical knowledge as it then existed. The fourth and last appeared between the years 1843 and 1855, and extended to six vols., the last volume being edited, after G.'s death, by Schlossberger and List. An English translation of this edition (under the auspices of the Cavendish Society), with important additions by Mr Watts, the translator, is now in course of publication, and nearly completed.

GMUND, a town of Württemberg, in the circle of Jaxt, stands in a beautiful and highly cultivated

district on the Rems, 29 miles east-north-east from Stuttgart. G. has important manufactures of *bijouterie* and hardware, and carries on spinning and stocking-weaving. Hops are produced in the neighbourhood in great quantity. G. was formerly an imperial free city, and in the middle ages had a population of 18,000. It was added to the kingdom of Württemberg in 1803. Pop. 6267.

GNAPHALIUM. See CUDWEED.

GNAT (*Culex*), a genus of dipterous insects, having the wings laid flat on the back when at rest; the antennæ thread-like, 14-jointed, feathery in the male, and hairy in the female; the mouth furnished with a long projecting proboscis, adapted for piercing the skin of animals and sucking their blood. They are said to feed also on vegetable juices. The species are numerous, and abound in almost all parts of the world, particularly in marshy regions; and some of them, under the name of Mosquitoes (q. v.), are known in many countries as most annoying pests. An irritating fluid, injected through the proboscis, makes their punctures painful, and causes swelling. The proboscis of a gnat is an extremely interesting microscopical object. It is a membranous cylindrical tube, clothed with minute, feather-like scales, and terminated by two lips, which, when closed, form a kind of knob, and by six sharp bristles or very small lancets. The female gnats have the most powerful proboscis, and are the principal blood-suckers. Some persons are much more liable to the assaults of gnats than others. The flight of gnats is very swift, and the extremely rapid vibration of their wings causes the loud and sharp buzzing sound, which so often prevents sleep when even one of these insects has found its way into a bedroom on a summer night. The eggs of gnats are deposited on the

admitted to the *tracheæ* or air-tubes. The pupæ also inhabit water, and are active; they remain almost constantly at the surface of the water, with the body recurved; and the respiratory openings of the air-tubes are now in the thorax.—The Common G. (*C. pipiens*) is of very wide geographic distribution. It is about three lines in length, brown, with whitish rings on the abdomen, the wings unspotted. It so abounds in some of the fenny parts of England that beds are occasionally surrounded with gauze curtains, as in India on account of mosquitoes. It is extremely abundant in Lapland and Iceland.—A number of genera, allied to *Culex*, are united by many entomologists into a family called *Culicidæ*.

GNEISS, a term introduced from the German, as the name for a variety of Metamorphic rock, which has the same component materials as granite, and differs from it only in these materials being arranged in layers, rather than in an apparently confused aggregated mass. The minerals of which it is composed are quartz, felspar, and mica. The mica is sometimes replaced by hornblende, producing a gneiss corresponding to the variety of granite called Syenite. The different ingredients occur in various proportions, altering the character and appearance of the gneiss accordingly. It is often difficult to determine hand specimens of gneiss; for, on the one hand, they are sometimes so crystalline that they resemble granite, while, on the other, the schistose varieties approach so near to mica-schist, that even in the field, under the most favourable circumstances, it is not easy positively to separate them.

Gneiss was originally deposited as sand or mud, and has been converted into a hard tough crystalline rock by long and continuous subjection to metamorphic action, induced, perhaps, chiefly by heat. It has generally been considered as an azoic rock, that is, deposited before the existence of life on the globe. The older strata, classified by Logan under the title Laurentian, the equivalents of which have been recently observed by Murchison in Scotland, have as yet proved destitute of fossils, but this may be owing to the extreme metamorphism they have undergone. The Cambrian and Silurian strata of the north of Scotland have also been to a large extent converted into gneissose rocks, which contain intercalated with them fossiliferous limestones. It would seem, indeed, that gneiss and its allied stratified rocks are not necessarily 'primary rocks,' but may occur wherever an agency sufficiently powerful has acted upon ordinary sandstone and shale.

GNESEN, a small town of Prussia, is situated in a district abounding in hills and lakes, in the province of Posen, and thirty miles east-north-east of the town of that name. It was the earliest capital, and is said to be the oldest town of Poland. Pop. 7765.

GNETA'OEÆ. See SEA GRAPE.

GNOME (Gr. *gnome*), a pithy and sententious saying, commonly in verse, embodying some moral sentiment or precept. The gnome belongs to the same generic class with the proverb; but it differs from a proverb in wanting that common and popular acceptance which stamps the proverb, as it were, with public authority. The use of gnomes prevailed among all the early nations, especially the Orientals; and the literatures, both sacred and profane, of most countries abound with them. In the Bible, the book of Proverbs, part of Ecclesiastes, and still more the apocryphal book of Ecclesiasticus, present, so far as regards language and structure, numberless illustrations of the highest form of this composition. The other books of the Old

Gnat, magnified :

1, insect depositing eggs; 2, insect escaping from pupa case; 3, larva of gnat; 4, floating raft of eggs.

surface of shallow stagnant water, placed side by side, united by an unctuous matter, and fastened to the bottom by a thread, which prevents their floating away. They are soon hatched; indeed, a single summer sees several generations of gnats. The larvae are to be seen in immense numbers in stagnant waters; they are of an elongated worm-like form; are destitute of feet, but swim and dive by means of fin-like organs; they feed on insects, and also on vegetable substances; and often suspend themselves at the surface of the water, head downwards, for the purpose of respiration, by means of radiating bristles attached to a long spiracle or tube at the caudal extremity of the body, by which air is

Testament contain many examples; and in the New Testament the familiar lessons of our Lord are frequently presented in this striking form, which was peculiarly adapted to impress and move the classes whom he addressed. The Indian, the Arabian, and the Persian literatures also are rich in gnomes, as are those of the northern nations. But the most interesting form which they have taken is that in which we find them in Greek literature, in which the writers who have cultivated this form of composition are known as a distinct class—the Gnostic Poets (*gnomistoi*). The Greek gnome is commonly couched in the elegiac distich; and the most celebrated gnostic poets were Solon, Theognis, Phocylides, Simonides, Tyrteus, and Xenophanes of Colophon. The most remarkable of these is Theognis, whose gnomes extend to above 1200 lines. The remains of gnostic writers have been repeatedly edited under the title of *Gnomici Poetae Graeci*, from the days of Melancthon downwards. The standard editions are those of Bekker (1815) and Welcker (1826). There is, moreover, a popular edition by Brunck, which is reprinted in the Tauchnitz Classics; and the gnostic poets are also commonly included in the collections of Minor Greek Poets.

In Latin literature, the *Disticha* of Dionysius Cato, the authorship of which has proved so fertile a source of controversy, may be mentioned as belonging to the class of gnomes.

GNOME, the name given in the cabalistic and mediæval mythology to one of the classes of imaginary beings which are supposed to be the presiding spirits in the mysterious operations of nature in the mineral and vegetable world. They have their dwelling within the earth, where they preside specially over its treasures, and are of both sexes, male and female. The former are often represented in the form of misshapen dwarfs, of whom the well-known 'Rübezahl,' or 'Number-nip,' of German legend is a familiar example. Pope, in the *Rape of the Lock*, and Darwin, in the *Loves of the Plants*, have drawn upon the more pleasing associations of this curious branch of mythology. See ELEMENTAL SPIRITS.

GNOMON. When a rectangle is divided into four parts by cross lines parallel to its sides, the sum of any three of the parts is called the *gnomon*. See Euclid, b. ii. prop. 5, and seq.—Gnomon has also a meaning in Dialling (q. v.).

GNOMONIC PROJECTION. See PROJECTIONS.

GNOSTICS (from Gr. *Gnōsis*, knowledge), the collective term for a number of early Christian sects which were known besides—with one insignificant exception—by special names derived from their respective founders. The word *gnosis*, when first applied to revealed religion, in many passages both of the Septuagint (for the Hebr. *Deah*) and the New Testament, expressed a full and comprehensive acquaintance with, and insight into, the received laws and tenets, ritual and ethical, and was consequently praised as a desirable acquirement; by St Paul even called a special gift (*Charisma*) (1 Cor. xii. 8, &c.). Gradually, however, there was—first by the Judæo-Alexandrine schools—ingrafted upon it a meaning more akin to that in which it was occasionally used by Pythagoras and Plato; it designated a knowledge of certain mysteries, which lay hidden beneath the letter of the religious records, and could be received only by a few superior minds, while the multitude had to be satisfied with the outward apparent meaning. The remarkable form of Christianity to which the word in this sense was applied, is a religious phenomenon as extraordinary as were the times and causes that gave it

birth. Rome had conquered well-nigh the whole of the then known civilised world, and within her vast dominions the barriers, which had hitherto separated the multifarious nations of east and west, were broken down. From the remotest corners of the empire philosophers and priests, scholars and teachers, flocked to Rome, to Athens, to Alexandria, and communicated to each other, discussed, and frequently amalgamated their widely differing creeds and systems to such a degree that the former national or personal individuality of opinion was almost effaced, making room either for a vacillating indecision, or at the best a shadowy and passive eclecticism. And while, on the one hand, Greek philosophy, which formed a principal part of the education of the higher classes, had become almost exclusively a Platonism, sliding into overt scepticism; on the other hand, the naturalisation in the Roman empire of a promiscuous Pantheon, whose gods were gathered from Egypt, Greece, Persia, India, and countries still more remote, had at length produced, out of an unparalleled mixture of religious ideas and fancies, a superstition so object and unnatural, that it too, at last, was ready to give place to despairing unbelief. Judaism, again, had outlived its political existence, and began to assert itself as a faith, independent of any state or dominion of its own; divided, however, into different schools, according to the more or less strict adherence to the letter of its written and oral laws. Nay, the influence of Hellenism had, among the Alexandrines, produced such effect that, of the living body of Judaism, little remained but a skeleton framework, round which allegory and symbol had woven their fantastic fabric. Christianity, as yet not clearly defined, swept all the more irresistibly over the regions from the Euphrates to the Ganges, the Nile to the Tiber, as it offered a code of morals sublime and yet simple, a faith human and withal divine, superior to any of the abstruse and exploded Polytheisms, to a world agitated to its lowest depths, and yearning for some new and more satisfying doctrine; while, at the same time, it denounced the stringent and severe ritual tenets of its mother-religion, Judaism, as inconsistent with the freedom of the human mind. Yet it was not to be expected that the old pagan creeds and the old philosophies would expire without a struggle. They made a last stand, and produced in their and the ancient world's dying hour Gnosticism. It sprang suddenly out of a monstrous chaos, a consummate religious eclecticism, bold, consistent, to a certain degree even sublime. The wildly opposite ideas of Polytheism, Pantheism, Monotheism, the most recondite philosophical systems of Aristotle, Plato, Pythagoras, Heraclitus, Empedocles, &c., together with the awe-striking Mysticism and Demonology which after the Babylonian captivity had created, in the very heart of Judaism, that stupendous and pre-eminently anti-Jewish science of Cabbala (q. v.)—all, it would appear, had waited to add something of their own to the new faith, which could not hold its own under all these strange influences. An open attack was no longer of any use; so, assuming the garb of the enemy, they sought to carry destruction into the centre of the hostile camp. Moreover, an aristocracy of mind, powerful and numerous as none had ever been before, could not but, even when it had outwardly assumed the new religion, loathe the thought of sharing it completely and unreservedly with the herd of freed and unfreed slaves around them, with the low and the poor in spirit; and the exclusiveness of Gnosticism was undoubtedly, next to the fascination of its dogmas, one of the chief reasons of its extraordinarily rapid propagation.

We have stated at the outset, that Gnosticism was but a general name for a great number of diverging Christian schools. But all these had some fundamental points in common, which we will attempt to specify briefly, as far as the fragmentary and adulterated nature of the evidence will permit; for unluckily, all we know of the G., we know from their Jewish and Christian adversaries, who confessedly took especial pride in representing them and their belief in their darkest hues.

There is a Divine Being, whose essence is love, grace, and mercy. He is enthroned in the highest height, enclosed in an abyss (*Bulhos*). He is the sum of being, He is silence, abstraction, incomprehensible, for human minds almost non-existing (*Out On*). The Mosaic Cosmogony has not seemingly, they said, brought us one step nearer to the solution of the problem of the creation. Out of nothing, nothing can come, notwithstanding a Divine Fiat; for God can, through his spiritual nature, have no connection whatever with corporeal things, and he could not have originally made them. They, therefore, assumed a pre-existing matter (*Hyle*), out of which the universe was merely formed. A corroboration for this opinion was found—according to the peculiar Gnostic mode of interpretation—in the two adjectives *Toku rabohu* (without form and void) (Gen. i. 2), applied to the earth, and which were by them interpreted as substantives (Kenoma, Kenon) intended to express the original substance of the universe (Cf. Gen. Rab. i.). Between this Hyle, or visible world, however, which was either represented as the darkness or shadow alongside the divine light, as a sluggish, stagnant mass, or as a turbulent, active kingdom of evil: and that supreme incomprehensible Being, whose goodness could have nothing to do with the evils of the world, no more than his perfection with its defects and misery, there existed a *Plerōma*, or fulness of Light. In this fulness dwelt embodied attributes of Divinity, the abstract ideas of Wisdom, Justice, Right, Power, Truth, Peace, and many more which had emanated or flowed out (in pairs, as some held, male and female) from the supreme central point, as rays innumerable flow out of the sun, as countless numbers from one unit, as echoes from a sound, or as, primarily, all the founts and rivers arise from the waters below. At the head of these emanations or *Æons* (Everlasting ones—like their source) which, descending lower and lower, form a link between heaven and earth, stands the *Nous*; and one of the lowest *Æons* is the *Demiurgos*. He is the real framer and master of the visible world, and partakes to a certain degree of its nature. On the nature of this *Demiurgos* (*Jaldabaoth*, *Archon*), however, the two principal divisions of Gnosticism, which might be termed Judæo-Alexandrine and Syrian respectively, widely differed. The former took him as the representative and organ of the highest God. It was he who had been put by the divine will over Israel, especially under the name of Jehovah. As other, though inferior, angels presided over the destinies of other nations, so this higher *Æon* had to protect the peculiar people of God. It was he, therefore, who revealed himself—he who gave the laws—he who sent the prophets. But in all this he acted rather as an unconscious medium; he was no more able to comprehend the full meaning of the ideas revealed through him in the Old Testament, than he understood the scope and significance of the creation. His principal attributes are justice and severity, which, carried out with stern consistency, become cruelty. These G. distinguished also among the Jews themselves, those 'after the flesh' who, confounding the likeness with the original, the symbol with the idea, took

the *Demiurgos* to be the supreme God, and those 'after the Spirit,' or Israelites indeed—the privileged few who, divining at least the veiled ideas of the supreme God, needed no such education by fear or hope, punishment or reward, at the hands of the *Demiurgos*, but rose above him in understanding and conception of things human and divine. The other principal party of the G., however, the Syrian, under the influence of the Parsic (Zoroastrian) Dualism, so far from considering the *Demiurgos* as an instrument of divinity, willing but poor in intellect, looked upon him rather as a rival, and consequently conflicting power. He is the primary evil opposed to the primary good. The divine germs which, according to both parties, had been communicated through the lowest emanations in their downward course to matter and to mankind, the *Demiurgos* of the Alexandrians had not known how to develop in a proper manner, but had weakened, sometimes neutralised them from want of knowledge, thus engendering all earthly sin and misery against his will, while the Syrian *Demiurge* spitefully and maliciously stifled these germs in order to wrest the power over the world from the Divine Being altogether. His base, revengeful, and withal limited nature, they said, is fully and clearly stamped upon the Old Testament—exclusively his work.

Man—in this all the schools were agreed—was divided into three classes, corresponding more or less to these predominant powers of the world: Divinity, Matter, and *Demiurgos*. There were first the spiritual men or *Pneumatikoi*, inspired by the highest God, striving towards him, with him; initiated into his counsels, understanding his essence. They were free from the yoke of law, for terrestrial nature had no power over them; they were the prophets, guiding, but not guided; the possessors of the true Gnosis. Diametrically opposed to these, as was Hyle to divinity, are the terrestrial men, *Sarkikoi* or *Choikoi*—of the earth earthy—who are tied and bound by matter; they can neither aspire to the height of spiritual men, nor are they to be ruled by the precepts of law. Between these stand the *Psychikoi*, the blind servants of the lawgiving *Demiurgos*, who are, through the restraints put upon them by his either stupid or spiteful precepts, free to a certain degree from the terrestrial powers, but they can never reach the height in which the pneumatics habitually dwell. And again, corresponding to these three classes of men, there were three principal religions; Christianity above, Heathenism below, Judaism in the intermediate space.

The two leading tendencies of Gnosticism, of which we have spoken, also manifested themselves, accordingly, in the view they each took of the person of Christ himself. According to both, he was the highest *Æon*, suddenly sent down by the Supreme Being, to rescue and reclaim certain higher natures—for the lowest stratum of men, the carnal or terrestrial, was irredeemably lost—which had either been led astray by the *Demiurgos*, or had become entangled in the net of matter. At the same time the harmonious combination of the human and divine in Christ, which the New Testament assumed, stood in direct opposition to the very basis of Gnosticism. The Visible and the Invisible, the Finite and the Infinite, God and Man, cannot combine: in this they all agreed. But while the Judaizing schools divided Christ into two distinct persons, one of heaven and one of earth, who had only become one at the baptism in the Jordan, and who had separated at the crucifixion; the other oriental section of Gnostics held that Christ's earthly manifestation in the flesh,

that his whole humanity, was a mere shadow or delusion.

It might well be asked how, with this extraordinary conglomeration of Monotheism, Pantheism, Spiritualism and Materialism, the G. could possibly take their stand on the Bible, which, from first to last, it would seem, denounces, and in the strongest manner, doctrines such as the foregoing. The only answer to this is, that they, and they only, were the *Pneumatikoi*—the Initiated. It was well for the other portions of mankind, the natural men, to take everything, including Scripture, and its historical as well as its dogmatical parts, literally. As in creation, so in the book; the G., guided by their inner lights, saw beneath the surface, and saw everywhere, the most complete affirmation of their peculiar ideas. If the Midrash (q. v.) gave the most fanciful and allegorical interpretations of the Old Testament, for the sake of inculcating moral principles, for edifying, elevating, comforting the congregation, but without the faintest pretence that any but the fixed traditional interpretation was binding and authoritative—Gnosticism, with a proud contempt of the laws of language and thought, did the same for its own purposes, but made its wildly symbolical and erratic interpretations of the religious records binding. We are far from saying that they were in all cases guilty of intentional deception, in the ordinary sense of the word; although they must frequently have known the real meaning to be totally opposed to their explanations, as most of their teachers were learned Jews; but they, like other enthusiasts, gradually lost the power of discriminating between that which was, and that which might be. Some, however, more consistent, assumed that Christ and his apostles had still been partially under the influence of the Demiurgos, and also that what they had taught, they had expressed in accordance with the blindness of those whom they addressed. Proceeding consistently, they by degrees excluded from the code most of the books of the New Testament, especially those in which there were distinct attacks against themselves; and substituted a number of other epistles and religious documents of their own in Greek and Syriac, such as the *Prophecies of Cain*, *Writings of Pachur*, *Paulins* by Valentinus and Bardesanes, *Gnostic Hymns* by Marcos, *Books of Adam, Enoch, Moses, Elijah, Isajah, &c.*, not to mention a host of writings by newly invented prophets of such peculiar names as Pachor, Barkor, Armagil, Barbelon, Balsamum, Lensiboras, &c. (Hier. ad Theod. iii. 6, &c.).

Practically, Gnosticism influenced the lives of its adherents in two totally distinct ways: according to the view they took of the nature and office of the Hyle and Demiurgos. The Hellenising Gnostics, striving to free themselves as much as in them lay from their stupid and degrading bonds, became ascetics, austere, rigid, and uncompromising. The oriental view, however, of the dualistic and antagonistic powers of light and darkness, good and evil, which was adopted by the other portion of the G., led them, on the other hand, to the practice of the grossest sensuality, in token, they said, of their utter contempt for matter, and still more for the Demiurgos—Body, and its enjoyments; everything terrestrial, in short, had as little to do with their mind, which was one with the Supreme Deity, as had matter with God. Transgression there was none, because there was no law; there could be no law for them who were better even than the angels—who were subject to none: a distortion of a dictum in the *Midrash*, that 'the law was not given to angels, but to mortal men,' and was therefore to be administered leniently.

They, indeed, knew not how to express to the full their utter contempt for this Jewish Jehovah, or Demiurgos. There were others among them who called themselves after the serpent (*Ophites*), which by tempting Eve brought into the world the blessing of knowledge, and had thus become its greatest benefactor. Others took the name of *Cainites* (*Balamites*), contending that Cain had been the primeval representative of Gnosis, as opposed to the *Pistia*, or blind unreasoning faith of Abel, the representative of the *Psychikoi* (the Jews)—Seth being the type of the *Pneumatikoi*. Another class of similar tendencies styled themselves simply *Antitacts* (opponents to the Law), a name indicative of their readiness to take under their especial protection, not only all those persons condemned in the Biblical records, but all the offences prohibited in them.

It is as hopeless a task to follow the development of this metaphysical and unique abnormality called Gnosticism, of which we have attempted here to give a faint outline, through the bewildering maze of its ramifications from its beginning in history to its final disappearance, as it would be to fully trace its component parts to their original sources. It sprang up in the first c., it had spread over the whole civilised world in the second, and it was fiercely and unremittingly combated from the second to the sixth c. by Judaism, Platonism, Neo-Platonism, and, above all, by Christianity. With respect to the relation of the Gnostics to the orthodox church, however, we must observe that they all the while feigned a naïve surprise at not being fully recognised as most faithful followers of Christianity, and members of the large Christian body. All they aspired to, they said, was to be allowed to form a small central circle within the large outer circle, to be a kind of theosophic community, consisting of the more advanced members of the church; indeed, they not only adhered, for the most part, to the outward forms of Christian worship, but occasionally even surpassed it in pomp and splendour. And such was the fascination Gnosticism exercised over the minds, that, had it not been for the innumerable schisms in its own camp, which prevented its alliance with the political power of the day, it would have stood its ground much longer. On its influence upon the Judaism of its time, as it is recognisable in many passages of contemporaneous Jewish literature; on its lasting influence upon Christianity; and on its frequent revivals in the middle and modern centuries, we can as little dwell here as on its embodiment in many philosophical systems, ancient and modern.

We can only take, in conclusion, a cursory glance over some of its principal schools, in giving a brief list of their founders (of whom, and their chief doctrines, special notices will be found), and the places where they flourished, without attempting to divide them minutely, as has been done in different ways, by Neander, Gieseler, Matter, Baur, Schaff, into Judaising and Christianising; speculative, practical and antinomian; dualistic and emanationistic; or to classify them strictly by origin and locality. Suffice it to mention, that among the precursors of Gnosticism are recorded some half-mythical personages, such as Euphrates, mentioned cursorily by Origen; Simon Magus, whose history, as given in the Acts, has been made the groundwork of innumerable legends; Menander, his successor; Cerinthus, the apostle of the Millennium; and Nicolaus, the father of the pre-eminently immoral sect of the Nicolaitans. Founders of special schools were, in Syria, Saturninus of Antioch, about 125 A.D. under Hadrian; Bardesanes of Edessa, 161 A.D., the author of many hymns, and who looked

upon the Holy Ghost as at once wife and sister of Christ; Harmodius and Marinus, his disciples; Tatian of Rome, the founder of the *Encratites*, who wrote a still extant *Oration to the Greeks*. Of Egyptian founders of Gnostic schools we may mention Basilides of Alexandria (125—140), who assumed 365 zodiacal signs or circles of creation, two Demiurgi, and a threefold Christ, and whose mystic use of numbers and names reminds us most strikingly of the Cabalistic *Geometria*; his no less famous son and follower, Ildorus, the author of a system of ethics; and Valentinus of Rome, who died 180 A.D. at Cyprus, a Jew—as indeed was Markos his disciple, and, very likely, Basilides and Ildorus. Of Valentin's successors who founded schools of their own, are mentioned besides Markos, Secundus, Ptolemy, Colarbasus, Heracleon, Theodorus, and Alexander. To the Syrians may also be reckoned the Ophites, Cainites, and Sethites (see above). In Asia Minor, we have Marcion about the middle of the second c., who is rather remarkable for his consistency in scornfully rejecting the whole of the Old Testament and all apostolic authority save Paul. His school flourished up to a very late period. Among non-localised G. may be enumerated the schools of Carpocrates and Epiphanius, the Bortonians, Antitacts (see above), Phibionites, Archontics, and a great many others.

Entw. d. Gnost. Syst.* (Berl. 1818); Mühlcr, *Urspr. d. Gn.* (Tübingen, 1831); Matter, *Hist. Crit. du G.* (Par. 1843—1844, 2d edit. 3 vols.); Baur, *Die Chr. G., &c.* (Tübingen, 1835). See also Neander's and Gieseler's *Histories of the Church*; Dorner's *Christology*; Bunsen's *Hippolytus and his Age*, and Grätz, *Gnosticismus und Judenthum*, besides many of the histories of Philosophy and of Christian dogma.

GNU (*Catoblepas*), a genus of ruminant quadrupeds, which naturalists generally rank with the antelope family (*Antilopidae*), but which some place in the ox family (*Bovidae*), and of which the best-known species has been often described as apparently

so much resemble those of zebras and quagga, that at a distance they may be readily mistaken for them. The size of the gnu is that of a large ass; the general colour is yellowish tawny. Both sexes have horns. The limbs are slender, like those of deer and antelopes. The gnu gallops with great speed. It has been usually represented as a very fierce animal, and certainly shews much ability to defend itself with its horns, when unable to escape from danger by flight; but when taken young, it is easily tamed, and readily associates with oxen, accompanying them to and from the field. There are two or three species, all South African, nearly resembling the common gnu, and one of them at least is very considerably larger. Their flesh is said to be palatable.

GO'A, a city of Hindustan, on the Malabar coast, in lat. 15° 30' N. and long. 74° E., while the dependent territory of the same name stretches in N. lat. from 14° 54' to 15° 45', and in E. long. from 73° 45' to 74° 28', containing 1066 square miles, and 313,262 inhabitants. G. was once the capital of the Portuguese dominions in India, but is now in a state of hopeless decay. It was valuable chiefly on account of its harbour, one of the best on the west coast of Hindustan, from which it was about 5 miles distant; but having the misfortune to be ravaged by the cholera in the beginning of the 18th c., most of the Portuguese left it, and settled nearer the sea, at Panjim or New Goa, which is the present seat of government, with a population of about 10,000. The inhabitants of the old city are almost entirely ecclesiastical, the place being the see of an archbishop, the primate of the Portuguese India. G. was conquered by Albuquerque in 1503, at which time it was inhabited by an Arabic people.

GOALPA'RA, a district of India which belongs geographically to Bengal Proper, but politically to Assam, stretches in N. lat. from 25° 40' to 26° 31', and in E. long. from 89° 42' to 91° 8', containing 3506 square miles, and about 400,000 inhabitants. On the N. it is bounded by the native state of Bhotan. Its capital, of its own name, stands on the river Brahmaputra, in lat. 26° 8' N., and long. 90° 40' E.

GOAT (*Capra*), a genus of ruminant quadrupeds of the family *Capridæ* (q. v.), so closely allied to the sheep that it is not easy exactly to define the distinction, although the common domestic goat and sheep are of widely different appearance. One of the most marked of the distinguishing characters is, that the horns of goats are directed upwards, backwards, and outwards, whilst those of sheep are more or less spirally twisted. Another character is the beard on the chin of the male goats, which is wanting in the sheep; but these characters are not perfectly constant. Perhaps a more constant character is the straight line of the face in goats, as compared with the arched line in sheep. The tail of goats is also much shorter than that of sheep. A curious but constant mark of distinction is the want of a small pit, producing a fatty secretion between the toes, in goats, which exists in sheep, and is peculiar to them. And another constant mark is the strong smell of male goats, particularly during the rutting season, which is wanting in sheep. Equally constant are the differences of temper and manners, goats being in a high degree curious and confident, and the very term *capricious* referring to their exhibition of the quality which it denotes. In both goats and sheep, both sexes are usually furnished with horns, the want of which is a variation apparently caused by domestication, and is most frequent in females. The horns and beard

Gnu (*Catoblepas Gnu*).

made up of parts of different animals, not only of the antelope and the ox or buffalo, but even of the horse. This species (*C. Gnu* or *Antelope Gnu*) is a native of South Africa; it has disappeared from the more settled parts of Cape Colony, but is to be seen in herds on the arid plains beyond these boundaries in company with the zebra or the quagga, and with flocks of ostriches. The form and action of gnus

of female goats are always smaller than those of the male. Some goats have horns three feet long.

Goats are found wild only in mountainous countries; they all exhibit a great aptitude for scrambling among rocks and bushes, are extremely sure-footed on narrow ledges and pinnacles, and display great strength and agility in leaping. They also prefer as food the leaves and small branches of shrubs, and the strongly aromatic herbs which abound in mountainous situations, to the herbage of the richest pastures. The Greeks and Romans sacrificed the goat to Bacchus, as an enemy of the vine. It is difficult in this genus to determine what are species and what are varieties. The COMMON or DOMESTIC GOAT (*C. hircus*) has existed as a

Common Goat (*Capra hircus*).

domestic animal from the earliest ages; it is frequently mentioned in the books of Moses, and formed a large portion of the flocks of the patriarchs. It adapts itself to almost all climates, and thrives under the care of man in the hottest parts of India and Africa, and with the protection only of a shed from the severity of winter, in the northern districts of Scandinavia. Amidst such diversity of circumstances, considerable diversity of breeds might be expected, and accordingly, besides the variety common in Britain, there are the Syrian Goat, the Angora (q. v.) Goat, the Cashmere (q. v.) Goat, all remarkable for the greater length and fineness of their hair; a beautiful dwarf variety from West Africa, called the Guinea Goat, and many others. Some of these, as the Syrian goat, have large pendent ears. In nothing does variation seem more readily to result from the influence of climate and other circumstances, than in the quantity and quality of the hair, and in the relative abundance of the two kinds of it, both of which are well exhibited in the common goat, the long soft hair, and the softer woolly hair beneath it. But in many other respects, also, the domestic goat is subject to variation, more than perhaps any other domestic quadruped except the dog.

Goats can be kept with advantage in situations too rocky, or where the herbage is too scanty for oxen or sheep. They were formerly kept in greater numbers in Britain than they now are. On some of the mountains of Wales and of Scotland, the goat is almost as completely wild as if it were indigenous, and even to get within shot of it is difficult. It is capable, however, of the most perfect domestication, and becomes extremely attached and familiar. It is apt, indeed, to prove a troublesome pet, and makes use of its horns, although not angrily, much more freely than is at all agreeable.

The uses of the goat are numerous. The flesh is good; that of the kid, or young goat, is in most countries esteemed a delicacy. The milk is very rich and nutritious, more easy of digestion than that of the cow, and is often useful to consumptive

patients. Some goats yield as much as four quarts of milk daily, although the average quantity is more nearly two. Both cheese and butter are made of goats' milk; they have a peculiar but not disagreeable flavour. Goats' milk is still very much used in Syria and other parts of the East, as it was in the days of the patriarchs. The skin of the goat was early used for clothing, and is now dressed as leather for many uses, particularly for making gloves and the finer kinds of shoes. The hair, which may be advantageously clipped annually, is used for making ropes which are indestructible in water, and for making wigs for judges, barristers, and ecclesiastical dignitaries. For the latter purpose, the hair of white goats is used. The use of the hair or wool of certain varieties of goat for making valuable fabrics is noticed in the articles ANGORA and CASHMERE GOAT. The horns are used for making knife-handles, &c., and the fat is said to be superior to that of the ox for candles. In Holland, goats are employed in drawing children's coaches, to which as many as four are sometimes harnessed together, and they are sufficiently tractable and obedient to the rein.

The goat generally produces two young ones at a time. A hybrid between the goat and the sheep has been produced, and it has been described as fertile, but there is no evidence of fertility except in connection with one of the parent races.

The origin of the domestic goat is with greatest probability traced to the AEGAGRUS (*C. Aegagrus*), which many naturalists confidently identify with it, and which is found on Caucasus and on many of the mountains of Asia. It is called *Paseng* in Persia. Its legs are longer than those of the domestic goat; its horns are very large, larger in proportion than those of any other known ruminant. —Another wild species is the JEMLAH GOAT (*C. Jemlaica*), which inhabits the district of Jemlah, between the sources of the Sargow and the Sanpoo, the most elevated range of Central Asia; very similar to which, if really distinct, is the JAHRAI (*C. Jahrai*) of Nepal. These, however, have no true beard, although they otherwise abound in long hair. —Other species or varieties of goat, of which the BOUQUETIN (q. v.) is one, are associated under the name IBEX (q. v.). —All the species are natives of the Old World.

GOAT, ROCKY MOUNTAIN (*Antelope lanigera*, or *Aploceros lanigera*), an animal of the antelope family, inhabiting the lofty peaks of the Rocky Mountains of North America, from about the 40th to the 65th degree of latitude. Its size is about that of an ordinary sheep, and its general appearance is not unlike that of a sheep of the Merino breed, its long straight hair hanging down in an abundant white fleece. The flesh is in little esteem as food, having a musky odour. —This animal has been called the *Sheep Antelope* and the *Wool-bearing Antelope*. It has been thought that its fleece might be available for some of the finer kinds of manufactures, and that it might be introduced with hope of advantage into the Highlands of Scotland.

GOAT-MOTH (*Cosmus ligniperda*), a lepidopterous insect of the same family with the Ghost-moth, *Hepialidæ*. The genus *Cosmus* has long antennæ; a large body, a very small head; the upper wings larger and longer than the lower. The larvae feed on the wood of trees, and the pupæ are enclosed in cocoons, made chiefly of the saw-dust which the mandibles of the larvae have produced. The G. is one of the largest of British moths, measuring from 3 to 3½ inches from tip to tip of its expanded wings. It is of a gray

colour, the upper wings mottled with white, and marked with many irregular black lines, the lower wings of an almost uniform brownish ash colour.

G. (*C. Europæus*), also called the Night-Charr, or NIGHT-JAR, from the sound which it produces; and not unfrequently, from the resemblance of its plumage to that of owls, the CHURN OWL or FRAY OWL. It is a summer visitant of Britain, coming very late, and departing generally very early; it is more common in England than in Scotland, although its migrations extend northward to Scandinavia, Siberia, and Kamtchatka. In winter, it retires from Europe altogether, passing to the south of the Mediterranean. It often haunts bushy places and grounds covered with brake. It scarcely makes a nest, but deposits two eggs in a depression of the ground, under shelter of a bush. Its whole length is about ten inches and a half. This bird is the *Caprimulgus* of Pliny, the *Algothelas* of Aristotle, both these names being exactly equivalent to the English G., and expressive of the ancient and long entertained popular notion, that this bird sucks the teats of goats, a notion probably founded on the habit—which, at all events, has been

Caterpillar, Chrysalis, and Imago of the Goat-Moth (*Cossus ligniperda*).

The larva is about 3 inches long when full grown, yellowish, the upper parts pink, the head black. The larva inhabits and feeds on the wood of willows, poplars, and elms, making holes large enough to admit the finger, and often causing the destruction of trees. It emits, when alarmed or handled, a peculiar and disagreeable goat-like odour, which cannot be removed from the hands even by frequent washings.

GOAT'S-BEARD. See SALISBURY.

GOAT'S RUE (*Galega*), a genus of plants of the natural order *Leguminosæ*, sub-order *Papilionaceæ*, of which one species (*G. officinalis*), a perennial herbaceous plant, about three feet in height, with pinnate leaves, long pointed leaflets, racemes of generally purplish or pink-coloured flowers, and upright nearly cylindrical pods, has been recommended for cultivation in Britain as a forage plant, on account of the great bulk of produce which it yields. It has, however, a peculiar smell, and is not relished by cattle unaccustomed to it. It is a native of the south of Europe.

GOATSUCKER (*Caprimulgus*), a genus of birds of the family *Caprimulgidae* (q. v.), having the upper mandible curved at the point, and furnished along each margin with a row of strong hairs or bristles (*vibrissæ*) directed forwards; the hind toe capable of being directed forwards; the claws short, except that of the middle toe, which is remarkably long, and serrated on its inner edge, so as to form a kind of comb attached to the toe. Although the bill is very short and weak, the gape is extremely wide, as if the head itself were divided. The goatsuckers feed on insects, perhaps chiefly on moths, whence they are called *Moth-hunters*, and pursue their prey either in the evening twilight or during the night, in a manner similar to bats and swallows. Like them, they seem to confine themselves very much to a limited space, in which they often pass and repass at no great height above the ground. They have great rapidity and power of flight. Of course, their great width of gape is favourable for the capture of insects. Goatsuckers are birds of light, soft plumage, in general minutely mottled with gray and brown. One species alone is found in Britain, the COMMON G. or EUROPEAN

Common Goatsucker (*Caprimulgus Europæus*).

observed in some of this family—of hunting insects under the bellies of grazing cattle. Species of this and closely allied genera are very widely distributed over the world.

GOBBE, or VOANDZOU (*Voandzeia subterranea*), an annual plant, allied to the kidney-bean, but of which the pod is thrust into the ground in the same manner as that of the Ground-nut (*Arachis hypogæa*, see ARACHIS), to ripen the seeds there. It is a native of the north-east of South America, and of some parts of the west of Africa. Its seeds are used as food, being wholesome and agreeable when boiled.

GO'BBO, GOBBIO, or GOMBO. See HIBBOW.

GO'BELINS. See TAPESTRY.

GOBI, DESERT OF. See SHAMO.

GO'BELINS AND BOGLES, familiar demons of popular superstition, in Fr. *gobelins*, Ger. *hobold*, Gr. *kobalos*, a spirit which lurks about houses. It is also called hobgoblin, perhaps a corruption of hopgoblin. Some have derived the word goblin from the French *gobier*, to swallow, to devour; and others the words elf and goblin from the Guelphs and Ghibellines, each name being used by the other party as a name of terror. Goblin is used in a serious sense by Shakespeare in *Hamlet*, where the ghost is supposed to be a 'spirit of health or goblin damned.' *Gobelet*, in French, is applied to juggler's tricks and instruments, and our word goblet comes from the juggler's cup.

Bogle, bogle-boe, or bugaboo, may be from the Welsh *brogwyl*, to terrify; and boe or boo, a sound. Bugaboo was the popular name of wide-mouthed, ugly pictures, formerly carried in May-games. Warton

says Boh was the designation of a fierce Gothic chieftain, whose name was used in after-times to frighten children. The belief in benevolent and malevolent spirits belongs to all countries, and appears to be as old as the world.

GOBONY, in Heraldry, the same as *Componé* (q. v.). A gobonated bordure is frequently carried in place of the baton sinister, not only by the lawful issue of bastards, who, after the third lawful generation, are considered entitled to make the change, but by bastards themselves. See **BASTARD BAR**.

GOBY (*Gobius*), a genus of acanthopterous fishes, the type of the family *Gobiidae*. This family is distinguished by the thinness and flexibility of the rays of the dorsal fin; by the union—in most of the genera—of the ventral fins, which are thoracic, into a disc more or less capable of being used as a sucker; by the want of an air-bladder; and by a long intestinal canal without cœca. The Blenny (q. v.) family (*Blenniidae*) have by some ichthyologists been united with the Goby family, whilst others unite with them the *Discoboli* (q. v.). The true gobies (*Gobius*) are generally small fishes, some of them inhabiting the shallow water of the coasts, and others found in deeper water; the species very numerous, and found in the seas both of the northern and southern hemispheres. They are very interesting on account of their habits; and are of the number of nest-building fishes, employing *algæ* and grass-wrack (*Zostera marina*), in the spring season, for making their nests. When the female has deposited her eggs in the nest, the male watches over them till they are hatched. There are several British species, the largest of them—the **BLACK GOBY**

The Black Goby and the One-spotted Goby
(*Gobius niger* and *Gobius unipunctatus*).

(*G. niger*)—about five or six inches long, some of them pretty common on all parts of the coast, and much in request for aquaria, of which they are among the most interesting occupants. They are often found in rock-pools on the coast. The disc formed by the ventral fins is often used for adhesion to stones. Most of the gobies prefer seas of clayey or muddy bottom, in which they excavate canals to pass the winter in. The species are more numerous in the Mediterranean than in the British seas.—The Goby family includes the Dragonets (q. v.), and several other interesting genera, among which are the *Boleophthalmi* of the Chinese seas, remarkable for their power of thrusting out their eyes in order to look around them.

GOD (Lat. *Deus*; Gr. *Theos*), the self-existent and Supreme Being, creator and preserver of all things, and the object of human worship. The name is of Saxon origin. The idea is more or less definitely expressed in every language, as it may be said to be in some form or another a universal element of the human consciousness. There have been many nations, indeed, in every age of

the world, that have been far from attaining any such conception of God as is expressed above. The Supreme has been to them the conception not of a single Being, but of many beings superior to man, and claiming his worship. In the general history of the world, polytheism precedes monotheism; the idea of many gods goes before the idea of one God, infinite and self-existent.

The general character of polytheism is everywhere the same.—A dualistic conception of nature and life underlies it, and shews itself in varied expressions. In looking forth on nature—in looking within himself—man seems to see two principles striving for the mastery—an active and passive, a creative and recipient principle—a good and evil, a productive and destructive, a joyous and gloomy agent. On one side, there seems a power rich, benignant, and gracious, giving light to the day, verdure to the spring, abundance in autumn, scattering fecundity and blessing around; on the other side, there seems a power cruel and malevolent, quenching the light in darkness, consuming the verdure and fertility with scorching heat, or destroying them with cold. These contrasts seem eternal—they take possession of the imagination, and clothe themselves in diverse shapes. In every polytheistic religion, they will be found in the recognition of male and female, of good and evil divinities—Baal and Baaltis, Baal-Adonis and Baal-Moloch, in the old Phœnician religion; Osiris and Isis and the evil principle, Typhon, in Egypt; and the more familiar opposites of Ahirman and Ormuzd, Jupiter and Juno, &c. The dualism assumes various shapes, now male and female, productive and passive; and now good and evil, conservative and destructive.

Whether this dualistic mode of conception, and the polytheistic view of nature that springs from it, be a later or an earlier type of thought than the monotheistic, has been a good deal disputed. Some see in it the corruption of monotheism—the worship of the Supreme gradually falling to a worship of the great forms of nature which most strikingly represent Him—the sun and storm, the light and darkness, &c. Others, again, regard the polytheistic as the primitive view of nature, above which man gradually rises, by the growth and exercise of his reason. There is truth in this latter view, even to those who believe that man originally received a Divine Revelation, which he has gradually corrupted. Polytheism is the natural religion of savage tribes throughout the world; and as man advances in civilisation, he rises to purer and more comprehensive conceptions of Deity. His reason compels him to recognise the One in the many everywhere, to carry up all his conceptions into a unity. Polytheism, consequently, everywhere disappears before the march of civilisation. It is incompatible with the lowest stage of speculative development.

But while the growth of reason and the rise of speculation everywhere destroy polytheism, they do not necessarily substitute a genuine monotheism—the doctrine, that is to say, of one living and true God, infinite in power, wisdom, goodness, and truth, a free personal Being exalted above the world, and apart from it, yet intimately related to all its creatures, who ‘suffereth not a sparrow to fall to the ground without his permission.’ This is the doctrine of Christian theism, as opposed alike to polytheism (the doctrine of many gods), pantheism (the doctrine that all things are God, that God is a unity, yet only a unity of comprehension, not a self-subsistent and independent unity), and atheism (the assertion that there is no God).

The course of argument on which the theistic conclusion supports itself may be sketched as follows: There are everywhere in the world the traces

of order; a unity of plan or design, shewn in many beautiful effects, pervades creation. Science is always more unfolding it. Of the fact of this order or unity of plan, there is no question. The progress of science, if nothing else, has effectually exploded the old dualistic or polytheistic conception of nature. What appeared to be the result of opposing principles, is really found to be the issue of general laws working on some great although unexplored scheme of harmony. There is no disturbance, no disorder; amidst the infinite diversity of nature—order reigns universally.

But this 'order,' what is it? The mere recognition of order does not necessarily imply the recognition of God—of a 'Being all-powerful, wise, and good, by whom everything exists.' The materialist and pantheist equally admit the fact of order, but equally deny the theistic conclusion founded upon it; and the argument, accordingly, is carried up from nature and its facts to a higher region of discussion. Whence arises the conception of order—of design? Nature illustrates it, but nature does not itself give it. The general laws of which science speaks so much pervade all phenomena of creation, but they are not a part of these phenomena. 'Order' and law are ideas which we convey to nature, not which nature brings to us. They come from within, not from without. It is with mind, and not with matter that we start. The latter in itself presents a mere series of endless movements. It is in the presence of mind only that it assumes meaning and order. Mind is the true image of the Deity. We discern causation in nature, because we ourselves are agents, conscious of exerting power. We discern order in nature, because we everywhere bring our conceptions into a unity, and apprehend our several modes of consciousness with reference to the indivisible self which they all involve. 'In our life alone does nature live.' 'It is from the little world of our own consciousness, with its many objects marshalled in their array under the rule of the one conscious mind, that we are led to the thought of the great universe beyond—that we conceive this also as a world of order, and as being such by virtue of its relation to an ordering and presiding mind.'

The existence of Deity, therefore, is a postulate of the human consciousness. Recognise a living mind in man, independent of matter—a rational will, as constituting the essential and distinguishing element of his being—and the inference is inevitable of an infinite mind—a supreme will governing the world. A true natural theology is based upon a true psychology. A philosophy which denies to man a higher existence than nature, which would make his rational consciousness the mere growth of material conditions, leaves no ground of argument for the existence of Deity—for, as Jacobi says: 'Nature reveals only fate, only an indissoluble chain of causes (sequences), without beginning and without end, excluding with equal necessity both providence and chance. Working without will, she takes counsel neither of the good nor of the beautiful; creating nothing, she casts up from her dark abyss only eternal transformations of herself, unconsciously and without end. But man reveals God—for man, by his intelligence, rises above nature, and in virtue of this intelligence, is conscious of himself, as a power not only independent of, but opposed to, nature, and capable of resisting, conquering, and controlling her. As man has a living faith in this power superior to nature, which dwells in him, so has he belief in God—a feeling, an experience of his existence. As he does not believe in this power, so does he not believe in God; he sees, he experiences nought in existence but nature, and necessity, and fate.'

The argument for the existence of God rests, accordingly, on certain fundamental principles of our mental and moral being, such principles as causation and design, or final cause. It implies a spiritual philosophy of human nature. Apart from such a philosophy, theism has no argumentative basis, however it may prevail as a tradition or superstition.

But some philosophers have sought not merely to rest the argument for the existence of God upon such principles, but to evolve it in all its completeness from them alone. From a single datum of consciousness—sometimes from a single datum of experience—they have tried to construct, by processes of mere abstract reasoning, a 'demonstration of the being and attributes of God.' This has been styled the *a priori* method of argument, although to all the arguments to which this name has been given it does not strictly apply. The mode of argument, again, which reasons from special effects in nature to a First Cause, has been styled, in contradistinction, *a posteriori*. The argument from design, for example, as conducted by Paley and others, is *a posteriori*. The arguments of Descartes, and the 'demonstration' of Dr Samuel Clarke, are what have been termed *a priori*. Either of these modes of proof, taken by itself, has been rightly considered inconclusive by recent writers on natural theology. Mere *a priori* trains of reasoning fail to carry up the mind to any real and living conception of Deity; they yield merely a theoretical or abstract idea. Arguments such as Paley's and the Bridgewater treatises, again, are rather illustrations than arguments. They derive all their logical force from certain principles which are implied in their details, and without which these details could have no bearing on the existence of God. The very idea of Design itself is such a principle. It is the die which the mind stamps upon nature; it is not in nature itself. Any complete argument for the Being of God, therefore, involves equally *a priori* and *a posteriori* elements. The former are necessary as the rational foundation of the argument; the latter are necessary to illustrate, to give life and body to the general principles which lie at the foundation.

The Christian doctrine of the Godhead will be considered under the several names of TRINITY, SON OF GOD, and HOLY SPIRIT.

GOD, OFFENCES AGAINST. See SACRILEGE.

GOD SAVE THE KING (or QUEEN), the noble national anthem of Great Britain, and by adoption that of Prussia and the German states, and which is played and sung in every part of the British empire alike on solemn and festive occasions, has been a subject of controversy with respect to its origin. Its words are apparently imitated from the Domine Salvum of the Catholic Church service. In England, the authorship has been generally attributed to Dr John Bull, born 1563, in 1591, organist in Queen Elizabeth's Chapel, 1596, professor of music in Gresham College, and chamber-musician of James I. About the period of the discovery of the Gunpowder Plot, he composed and played on a small organ before the king an ode beginning with the words, 'God save great James our king.' He died at Lübeck, 1622. It does not appear, however, that this, or any other old composition of a similar title, had any connection with that which we now possess. Chappell, in his *Popular Music of the Olden Time*, and Dr Fink, a German musical antiquary, have settled the question; the honour of this great work, both words and melody, must be given to Dr Henry Carey, an English poet and musician, born in London about 1696, died 1743. The words and music were composed in honour of a birthday

of George II., and performed for the first time at a dinner given on that occasion in 1740 by the Mercers' Company of London. The words and music were first published in the *Harmonia Anglicana*, 1742, and appeared in the *Gentleman's Magazine*, 1745. The air, according to Dr Arne, has preserved its original form, but its harmonies have been modified by various artists; and the words were changed on the accession of William IV., and on that of Queen Victoria.

GODAVERY, or GODAVARI, one of the principal rivers of the peninsula of Hindustan, and the largest of the Deccan, rises within 50 miles of the Arabian Sea, and flows south-east across the peninsula into the Bay of Bengal. Its source is in the eastern face of the Western Ghauts, in lat. 19° 58' N., and long. 73° 30' E.; and its two mouths, diverging in lat. 16° 57' N., and long. 81° 49' E., enter the sea respectively in lat. 16° 48' and long. 82° 23', and in lat. 16° 18' and long. 81° 46'. About 23 miles above the head of the delta, the G. emerges at Polaveram from the Eastern Ghauts, through which it has passed with so moderate a descent as to be navigable in either direction. The southern arm of the G. admits vessels drawing eight or nine feet; and the northern one shews a depth of two or three feet more. Like tropical streams in general, the river varies greatly, according to the season, in breadth and depth. But a dam or annicut (see CAUVERY) has been constructed, so as to mitigate the evil for the purposes alike of navigation and of irrigation. The entire length of the G. is about 900 miles.

GOD-BOTE, an ecclesiastical fine, paid for crimes and offences against God. The word bote, the same as boot, is the old Saxon bot or bote, a reparation or satisfaction—a g. man-bote was the compensation due for the life of a man.

GODESBERG, a village of Rhenish Prussia, with a fine ruin, is situated on a conical hill in the midst of a plain, on the left bank of the Rhine, and four miles south of Bonn. It has a mineral spring, is a favourite summer residence, and has a population of 1170. It derives its name, not from Woden, who is said to have been worshipped here, but more probably from the Gau-ding, or Goding, the district court which may have held its sittings at this place. The castle was erected by Dietrich, the Archbishop of Cologne (1208—1213), with materials taken from the ancient chapel of St Michael, the ruins of which are still standing near the castle. In 1582, Gebhard, the deposed archbishop, took refuge here, and intrusted the castle to a Dutch garrison. It was, however, soon after taken by his successor, on which occasion it sustained much injury. During the Thirty Years' War, it was alternately in the possession of the Swedes and the Imperialists, and was finally almost demolished by the French. Only one fine tower, 90 feet in height, is still standing. It commands a magnificent prospect of the Siebenbirge and great part of the valley of the Rhine, and is, on this account, much visited by strangers.

GODFATHER and GODMOTHER, the person who, by solemnly presenting to the minister of baptism the candidate for that sacrament, which is regarded as a new spiritual birth, is reputed to contract towards the newly baptized the relation of spiritual paternity or maternity. The effects of the usage are differently estimated in the different communities.

In the Roman Catholic Church, the parties presenting a child for baptism are called, from the spiritual parental relations which they contract, godfather' (*patrinus*) and 'godmother' (*matrina*); and from the engagement into which they enter on

behalf of the baptized, 'sponsors' (*sponsores*). The spiritual bond resulting from this relation is regarded as a species of kindred (whence the name *goestip*, or God-sib, *spiritually akin*), and constitutes, by the canon law, an impediment of marriage between the sponsors upon the one hand and the baptized and the parents of the baptized on the other. Anciently, this impediment arose also between the sponsors themselves, who were often very numerous, and extended besides to the other members of the kindred; but the Council of Trent limited the number of sponsors to 'one or two,' and restricted the matrimonial impediment within the limits above described. The parents of the baptized are not permitted to act as sponsors in the Roman Catholic Church, one of the objects of the institution being to provide instructors in case of the death of parents; nor are members of religious orders, because their inclusion within their convent is supposed to render it impossible for them to discharge permanently and regularly the duties of instructors to the newly baptized. In the Roman Catholic sacrament of confirmation also, the candidate is commonly presented by one sponsor, generally, though not necessarily, of the same sex with the candidate for confirmation. It is difficult to assign the precise date of the origin of this institution. No trace of it occurs in the New Testament, but it is believed to have been in use in the 2d c., and it certainly was an established practice in the fourth.

In the Church of England, two godfathers and a godmother are required at the baptism of a male, and two godmothers and a godfather at that of a female. In order to be admitted as such, the person must be baptized, must be of full age, acquainted with the Lord's Prayer, Creed, and Ten Commandments, and familiar with the fundamental truths of Christianity. No impediment of marriage arises in the English Church from the relation of the sponsors to the baptized. Practically, the usage in the Church of England has, for the most part, degenerated into a mere form; godfathers and godmothers usually giving themselves little concern in the future fate of the infant whose spiritual condition they become bound to watch over. In the Church of Scotland, and other non-Episcopal Churches, the parents of the infant occupy the place of sponsors; the father expressly taking the vows on the occasion.

GODFREY OF BOUILLON, Duke of Lower Lorraine, born about 1061, at Baisy, a village of Belgian Brabant, was the eldest son of Count Eustace II. of Boulogne, and Ida, sister to Gottfried or Godfrey, the Hunchback, Duke of Lower Lorraine and Bouillon, whom he succeeded in the government of the latter duchy in 1076. He served with great gallantry in the armies of the Emperor Henry IV., both in Germany and Italy; and it was from his hand that the competitor for the imperial crown, Rodolf of Swabia, received his deathblow at the battle of Merseburg. When the first Crusade was set on foot, the fame of his exploits caused him to be elected one of the principal commanders. In order to defray the expenses of the Crusade of 1095, he mortgaged Bouillon to the Bishop of Liege, and set out, accompanied by his brothers Eustace and Baldwin, in the spring of 1096. For a detailed account of his career up till the taking of Jerusalem, see CRUSADES. Eight days after the taking of Jerusalem, G. was proclaimed king by the unanimous voice of the crusading army; but the piety and humility of the conqueror forbade him to 'wear a crown of gold where his Saviour had worn one of thorns.' He declined the regal title, contenting himself with that

of Defender and Guardian of the Holy Sepulchre. The Sultan of Egypt, learning that the army of 30,000 Crusaders who had taken Antioch had dwindled away to 20,000, advanced against them with an army said to have amounted to 400,000 men; but G. gave him battle in the plain of Ascalon, and the victory gained on this occasion put him in possession of the whole of Palestine, a few fortified towns only excepted. He now directed his endeavours to the organisation of the new state; he installed a patriarch, founded two cathedral chapters, built a monastery in the valley of Jehoshaphat, and drew up laws. He died in 1100, and his body was interred on Mount Calvary, near the Holy Sepulchre. History represents this prince as a model of piety, valour, and all kingly virtues; and his praises have been worthily sung by Tasso in his *Jerusalem Delivered*.

GODIVA, Lady, patroness of Coventry. About the year 1040, Leofric, Earl of Mercia, and Lord of Coventry, then an important market-town, imposed certain onerous services and heavy exactions upon the inhabitants, of which they loudly complained. His wife, the Lady G., having the welfare of the town at heart, besought her husband to give them relief, and was so earnest in her entreaties, that at length, to escape from her importunities, the earl said he would grant her the favour, but only on condition that she would ride naked through the town, supposing, from the modesty of Lady G., that he had required an impossible condition; but he was surprised with the answer: 'But will you give me leave to do so?' As he could not in justice refuse, she ordered that proclamation be made that on a certain day no one should be away, or even look, from their houses, when, clothed only by her long hair, she rode through the town; and her husband, in admiration of her intrepid devotion, performed his promise. This circumstance was commemorated by a stained-glass window, mentioned in 1690, in St Michael's Church, Coventry; and the legend that an unfortunate tailor, the only man who looked out of a window, was struck blind, has also found commemoration in an ancient effigy of 'Peeping Tom of Coventry,' still to be seen in a niche of one of the buildings. By a charter of Henry III., 1218, a fair is held at Coventry, beginning on Friday of Trinity-week, and lasting eight days. The fair was opened with a grand civic procession, a part of which was, in 1678, the representation of the ride of Lady Godiva. These processions were continued at intervals of from three to seven years, until 1826. Some beautiful woman, who represented Lady G., was the principal figure, but many other historical and emblematic personages were introduced. In 1848, the procession was revived with great splendour, and the spectacle attracted more than 15,000 strangers. The fair of 1862 was opened with a similar procession.

GÖDÖLÖ, a market-town in Hungary, formerly the residence of the princely family Grassalkovich, is distinguished for its manorial castle, as well as for the surrounding parks. It was on the woody heights of G. and Isaszeg that the combined armies of Austria, under Prince Windischgrätz and Count Jellachich, were defeated in two bloody battles by the Hungarians under Görgei. On the eve of victory, Governor Kossuth held a conference with the generals Görgei, Klapka, and Damjanich, for laying down the principles of the famous Declaration of Independence, issued on the 14th of April 1849, by the diet at Debreczin. It was this declaration which served the emperor of Russia as a pretext for the invasion of Hungary.

GODOLPHIN, SYDNEY, EARL OF GODOLPHIN, an English statesman, was descended from an old Cornish family, and was born, it is thought, about 1640. After the Restoration he became one of the grooms of the bed-chamber to Charles II., was appointed one of the secretaries of state in 1664, and soon after first commissioner of the treasury; was twice despatched to Holland in 1678 on business of importance, and argued and voted for the exclusion of the Duke of York from the succession in 1680. Nevertheless, when the latter mounted the throne, G. (now Baron Godolphin of Rialton, in Cornwall) was made lord-chamberlain to the queen; and on the landing of the Prince of Orange, he was one of the commissioners sent by King James to treat with the invader—a difficult piece of business, which he is considered to have managed with much tact and prudence. William was not slow to perceive the admirable abilities of G., and in 1690 appointed him first lord of the treasury. In 1695 he was one of the seven lords justices for the administration of the government during the king's absence. In 1702, on the accession of Anne, he accepted the office of lord high treasurer, mainly at the solicitation of Marlborough, who paid him a splendid compliment by declaring that otherwise he could not venture to assume the command of the British armies, as he could depend on him alone for punctual remittances. G. fully realised the expectations of the great Captain. He raised the public credit, induced the queen to contribute £100,000 towards the war, firmly opposed the selling of offices and places, and increased the stipends of the inferior clergy. In 1706, G. was raised to the dignity of Earl of Godolphin and Viscount Rialton; after this period he took part with the Whigs, as being more patriotic and English than the Tories. The contest between him and Harley for the premiership, resulted finally in the defeat of G., who was dismissed from office in 1710. He died at St Albans, September 15, 1712, and was interred in Westminster Abbey. The title became extinct in his son Francis, second Earl of Godolphin. G. was the best business-man of his age. He had the clearest and quickest understanding, and liked to do his work in such a way that it would not require to be done over again. In an age of corruption, G. was believed to be incapable of bribery, and he never employed as his agents any except men of integrity. His 'talent for silence' equalled William's own.

GODOY. See **ALCUDIA**.

GOD'S TRUCE (Lat. *Tregua Dei*, or *Treua Dei*, from the Ger. *Treu*, true), one of the most singular among the institutions of the middle ages, which prevailed specially in France and the Germanic empire, but was also received for a time in the other countries of Europe. It consisted in the suspension for a stated time, and at stated seasons and festivals, of that right of private feud for the redress of wrongs, which, under certain conditions, was recognised by medieval law or usage. Private feuds, it is true, could only, by the medieval law, which was called *Faustrecht* and *Fehderecht*, be undertaken when judicial redress had failed or could not be enforced, and after formal notice had been served upon the party against whom they were levied. But even with this limitation, private feuds multiplied exceedingly. The public peace was subject to constant interruption; the weak were without resource; the strong bore down all by the terror of their arms; and the whole social framework was so utterly disorganised, that men, by one of those religious impulses of which this age offers so many examples, fell back upon the aid of the church, and invoked her influence, as the only effectual

means of staying the evil. It was in this crisis that the 'God's Truce' originated. In the end of the 10th c., a council assembled at Limoges, at which the princes and nobles bound themselves, by solemn vow, not only to abstain from all unlawful feuds, but also to keep the peace mutually towards each other, and to protect from violence all defenceless persons, clerics, monks, nuns, women, merchants, pilgrims, and tillers of the soil. A similar engagement was entered into in a council at Orleans in 1016; and the whole body of the bishops of Burgundy enforced it upon their flocks everywhere throughout that duchy. A plague which visited a great part of Europe soon afterwards gave a fresh impulse to the movement; and in the year 1033, the 'Holy Peace' was almost universally received, and for a time continued to be religiously observed. But as the old abuse began to revive by degrees, it was felt that the observance would carry with it more of religious authority, if, instead of being, as it had originally been instituted, universal, it was limited to certain times and days, which themselves had certain religious associations connected with them. Accordingly, in 1041, the bishops of Aquitaine limited the God's Truce to the week-days specially consecrated by the memory of the Passion and Resurrection of Christ—that is, from the sunset of Wednesday to sunrise of Monday. The same decree was renewed at Narbonne in 1054, and at Troyes in 1093. At Clermont, in 1095, it was extended to the whole interval from the beginning of Advent to the Epiphany, and from the beginning of Lent to Pentecost, to which times were afterwards added several other festivals. These enactments were adopted or renewed at several later councils; and although they were often disregarded, it is impossible to doubt that they had a wide and lasting influence in mitigating the evil against which they were directed. This singular institution fell gradually into disuse, and at last disappeared altogether, when the right of private redress was restricted, and at last entirely abolished, by the law of the empire.

GODWIN, WILLIAM, an English author, was born at Wisbeach, in Cambridgeshire, March 3, 1756. His father and grandfather were Presbyterian ministers, and he was educated to the same profession, first at a school at Norwich, to which place his father had removed in 1767, where he made rapid progress in classical studies, and afterward at a Presbyterian college at Hoxton, where he pursued his theological studies. From 1778 to 1783, he was minister to a congregation in the neighbourhood of London; but the zeal with which he first entered upon his duties declined, and a change in his theological opinions made it necessary for him to resign his charge. His only resource was to remove to the metropolis, and engage in literature. His first work, a series of *Historical Sketches*, in the form of sermons, was unsuccessful, and he was reduced to penury and despair; but they made him acquainted with Fox, Sheridan, and other Whig leaders, and he turned his attention to politics. The American revolution, closely followed by that of France, excited the public mind, and G. wrote his *Inquiry Concerning Political Justice*, 1793. This was followed by *The Adventures of Caleb Williams*, a remarkable novel, which is still popular, and *The Iron Chest*, a tragedy, which keeps its place upon the stage. An able defence of Horne Tooke and others, published in the *Morning Chronicle*, advanced his reputation; and in 1797, he published *The Inquirer*, a collection of essays on morals and politics. About this time, he formed an alliance with Mary Wollstonecraft, the celebrated author of the *Rights of Woman*, and adopted and defended her extreme

social views. After some months, however, they yielded so far to custom as to be married. His wife died a short time after in giving birth to a daughter, who afterwards became the second wife of the poet Shelley. In 1799, he published *St Leon*, a romance; and the next year visited Ireland, where he associated with Curran, Grattan, and other eminent Irish political leaders. He also consoled himself for the loss of his wife by writing her Memoirs. In 1801, he married again, and had a son, who died of cholera in 1832. To secure a more certain support, G. and his wife opened a circulating library, but he also worked indefatigably with his pen to the end of his life. He wrote many school-books, an admirable *Life of Chaucer* (1801); *Fleetwood*, a novel, 3 vols. (1805); *Mandeville*, in 1817; a *Treatise on Population*, a refutation of Malthus, in 1820; a *History of the Republic of England*, in 4 vols. (1824—1828); *Cloudeley* (1830); *Thoughts on Man* (1833). As he grew old, he modified his opinions on politics and society, and especially on marriage, which he warmly commends in some of his later works. Being now 77 years old, he was appointed to a place under government, which removed him from the apprehension of want; but he knew not how to be idle, and wrote *Deloraine*, a novel, and the *Lives of the Necromancers*. Many of his works were translated into foreign languages. He died in London, April 7, 1836.

GODWIN, EARL OF WESSEX, a famous Saxon noble, was born towards the end of the 10th century. Originally, it is said, he followed the occupation of a cow-herd; but having found means to ingratiate himself with Ulfr, the brother-in-law of King Canute, the latter gave him his daughter in marriage, and he soon became one of the most powerful of the English nobles. More than any other person, he contributed to the elevation of Edward to the English throne (1044 A.D.); and the principal reward of his services was the marriage of his beautiful and accomplished daughter Editha with the English king. This union, however, was not a happy one. Editha was cruelly neglected by Edward, and her father, on account of his dislike of the Normans, incurred the royal enmity. His estates were seized, and given to favourites, and he and his family fled. Queen Editha was made to feel even more bitterly than any one the misfortunes of her family. Her own husband seized her dower; he took from her her jewels and her money, 'even to the uttermost farthing;' and allowing her only the attendance of one maiden, he closely confined her in the monastery of Wherwell, of which one of his sisters was lady-abbess. Meanwhile, shoals of Normans visited England for the purpose of making, or rather getting fortunes. Among Edward's most favoured guests for a time was Duke William of Normandy, better known as William the Conqueror. The banished earl, however, had not been idle; through frequent correspondence with his countrymen at home, he kept alive the antipathy of the English to the Norman favourites of Edward, and in the summer of 1052 he landed on the southern coast of England. The royal troops, the navy, and vast numbers of the burghers and peasants, went over to him; and finally the king was forced to grant his demands. The Normans were for the most part expelled from the country, the G. family was restored to all its possessions and dignities; and at a meeting of the Witenagemote, 'the earls and all the best men of the land' declared that the foreigners alone were to be held guilty of the late dissensions that had distracted the country. G. did not long survive his triumph; he died April 7, 1054.

GODWIT (*Limosa*), a genus of birds of the family *Scelopacidae*, with very long bill, slightly curved upwards, and long slender legs, great part of the tibia bare. All the species frequent marshes and shallow waters, chiefly those of the sea-coast, where they seek their food by wading and by plunging the long bill into the water or mud like snipes. They sometimes also run after small crustaceans or other animals, and catch them on the sands, from which the tide has retired. Two species occur in Britain, the **BLACK-TAILED G.** (*L. melanura*) and the **BAR-TAILED G.** (*L. rufa*), both birds of passage, and not

Bar-Tailed Godwit (*Limosa rufa*).

unfrequent visitors of the marshy parts of the east coast of England, where the first occasionally breeds; but both generally breed in more northern countries, and are seen in Britain chiefly in their migrations northward and southward. Both species are very widely distributed over Europe, Asia, and Africa. The females are rather larger than the males, and the whole length of the female black-tailed G., which is rather the largest species, is about 17 inches, the bill alone being four inches long. They are much esteemed for the table, and are sent from Holland to the London market, which also receives some from the fens of Lincolnshire.

GOES, or TERGOES, a town and fortified seaport of Holland, in the province of Zeeland, is situated in a fruitful district in the island of South Beveland, about $3\frac{1}{4}$ miles from its northern coast, and 17 miles west of Bergen-op-Zoom. It is well built; has a harbour formed by a canal communicating with the East Scheldt, ship-building docks, besides an active trade in hops, salt, and agricultural produce. Pop. 5400.

GOETHE, JOHANN WOLFGANG VON, the acknowledged prince of German poets, and one of the most highly gifted and variously accomplished men of the 18th century. He was born in the year 1749 at Frankfurt-on-the-Maine, where his youthful years were spent. His father, Johann Kaspar Goethe, was an imperial councillor, in good circumstances, and in a respectable position. In the year 1765, he went to the university of Leipsic, of which Ernest and Gellert were then the most notable ornaments. As a student, he pointed, by external profession, towards the law; but his real studies were in the wide domain of literature, philosophy, and above all, life and living character. In the year 1770, he went to Strasburg, to finish his juridical studies; but here also anatomy and chemistry, Shakspeare, Rousseau, and architecture—anything rather than the statute-book—occupied his time and exercised his soul. Here it was that one of the earliest, certainly the most

famous of those youthful love-adventures took place, which, in his biography, as in that of Robert Burns, play such a prominent part—the well-known affair of Frederica Brion of Seisenheim. With regard to these matters in general, it may be said that he was more readily moved to love than intense in love; and that the objects of his admiration generally seem to have had more reason to boast of the delicacy of his susceptibility, than of the perseverance of his devotion. How far there was anything more than commonly culpable in these connections, will always be a question; certain it is that they will always tarnish to some extent the otherwise fair reputation of the poet. The female sex will never forgive the man who was so light to lend his heart, and so fearful to give his hand; and British morality will always be inclined to pass a severe judgment on the man who, professing the profoundest subjection to law and order in everything else, seems to have shrunk from the golden clasp of legitimate marriage as from some conventional shackle, which a free and great nature should avoid. In the year 1771, the young poet, now 22 years of age, took his degree as Doctor of Laws, and went for a short while to Wetzlar on the Lahn, the seat of the imperial chamber of the then German empire, and which afforded peculiar facilities for young men engaged in the study of public law. Here, however, as in other places, his knowledge of the human heart, and of human character, altogether overgrew his professional studies; and Wetzlar became to him the scene of the famous *Sorrows of Werther*, a glowing leaf from the life of the human soul, full of interest and beauty at all times, but which, in the then state of European thought and feeling, stirred the whole literary mind of Europe like a breeze sweeping over a forest. The book was not published till 1774. After returning from Frankfurt, G. spent some years in his native city, engaged chiefly in literary productions. His first great work was *Gotz von Berlichingen*, translated into English by Sir Walter Scott, published at Frankfurt, 1773, which at once set the Germans free from the painful constraint of French and classical models, and opened up to them that career of bold originality, which they have since prosecuted in so many departments of literature, learning, and speculation. In the year 1775, G., who had had the good-fortune to gain the good opinion of Karl August, Grand Duke of Saxe-Weimar, accepted an invitation from that prince to settle in his little capital, since become so famous as the Athens of the great legislative age of German literature. Here the poet became a little statesman; and occupying himself in various ways in the service of his benefactor, passed quickly through stages of court preferment, till, in 1779, he became 'actual privy-councillor,' at the age of 30, holding the highest dignity that a German subject could then attain; a great, a rich, and an influential man. In 1782, he received a patent of nobility; and in the following years, till 1788, travelled much in Switzerland and Italy, of which last journey we have the beautiful fruits in *Iphigenia*, *Egmont*, *Tasso*, and the *Venetian and Roman Elegies*. Of this last work, thoroughly German both in form and feeling, the heroine was Christiana Vulpius, a highly attractive though not a highly gifted woman, who bore him a child—his eldest son—in 1789; but whom, though he always treated her as his wife, he did not formally marry till 1806. In 1792, he took part in the German campaign against France, of which he has left a memoir. In the year 1815, he was made minister of state. After the death of the grand duke, in 1828, he lived much in retirement, occupied occasionally with poetry, but much

more intensely and constantly with the study of nature and the fine arts, which from his earliest years had possessed the strongest attractions for him. He died in March 1832, in his eighty-fourth year.

To give a detailed account of the literary and scientific productions of G.'s pen, is altogether impossible within the limits of the present work; much less can we attempt any detailed criticism of these works. The best source of reference to the more English reader is the biography of the poet, by G. H. Lewes; along with which may be taken G.'s interesting conversations with Eckermann, translated by Oxenford. On the general character and literary position of G., however, a few words are necessary. It is as a poet, no doubt, that this remarkable man is generally known and recognised in this country; but it is not as a poet only that a just measure can be taken of his intellectual calibre or of his European significance. It is as poet, thinker, critic, and original observer of nature, all combined in one admirable harmony, that his rare excellence consists. We do not find in literary history any intellect that can fitly be placed on the same platform with G.; that presents, in such grand and graceful completeness, so much severe thought, combined with so much luxuriant imagination; so much accurate science with so much playful fancy; so much simplicity with so much art; so much freshness and originality of productive power, with so much justness and comprehensiveness of critical judgment. As a dramatist, G. will not compare for a moment with the great masters of that art among ourselves. His English biographer detects in the constitution of his mind, most justly, 'a singular absence of historic feeling and dramatic power.' Not less correct is the judgment of the same writer when he says: 'Goethe was attached to character and picture, indifferent to action and event.' In this respect, the poet was a true type of his nation. As contrasted with the French and English, the Germans are deficient in nothing so remarkably as in stirring passion and progressive energy; the relation of G. to Shakespeare and the English dramatists is exactly the same. Nevertheless, *Faust* is a great poem, even a great dramatic poem, for it is full of dramatic scenes, though they are not sufficiently moved by the living current of dramatic action. *Faust* is essentially a German poem, and yet a poem which all foreigners can read and enjoy. It is the great drama of that moral and metaphysical questioning which thoughtful minds must go through in all times and places, but which has received the fullest and most fruitful development in modern Germany. Of the other poetical works of G., *Iphigenia*, *Hermann and Dorothea*, and *Tasso*, are those which most strongly bear the type of the ripe manhood of the author. The form and style of these classical works are characteristically Greek; by which we mean they are chiefly remarkable for profundity of thought and truth of feeling, expressed in the most simple, graceful, and unpretending manner. In soul, however, they are essentially German; and the most deep-thinking of the Germans are always the first to claim G. as the most German of all German poets in spirit, though very few great German writers have so carefully avoided the most characteristic German defects of style. In the extraordinary value which he attaches to 'the form,' G. authenticates himself everywhere as at once a great modern Greek and a great artist.

G. is a poet who is thoroughly relished only by those who understand thoroughly the German language, and whose minds are not so typically English as to exclude a ready sympathy with

German thoughts and feelings. With general English readers, for various reasons, Schiller will always be the favourite poet. Nevertheless, there has been a considerable amount of literary power in this country spent in the translation of G.'s works, specially of his great work, the *Faust*; of this, at least a dozen translations exist, the most notable being by Anster, Blackie, and Hayward. Some of the most beautiful of the lyric poems have been aptly rendered in a conjoint volume by Professor Aytoun and Theodore Martin.

GOG AND MAGOG, names several times used in the Bible, and the names given to the famous fi of giants in Guildhall, London. Magog is g of by the writer of Genesis as a son of J. Esau speaks of Gog, prince of Magog; G d Magog are spoken of in the Revelation. M is considered by some the father of the S ns and Tartars. The Persians have also b... arrived from Magog, and the Goths from Gog and Magog. The Caucasus is supposed by Bochart to derive its name from Gog Chasan—fortress of Gog. Our Guildhall giants boast of almost as high an antiquity as the Gog and Magog of the Scriptures, as they, or their living prototypes, are said to have been found in Britain by Brutus, a younger son of Atheneus of Troy, who invaded Albion, and founded the city of London, at first called Troy-novant, 3000 years ago. Albion, at this period, was inhabited by a race of tremendous giants, the descendants of the thirty-three infamous daughters of the Emperor Diocletian, who, having murdered all their husbands, were sent to sea in a ship, and were happy enough to reach Albion, where, cohabiting with wicked demons, they gave birth to the giants, whom the Trojans finally conquered, leading the last two survivors prisoners to London, where they were chained to the gates of a palace on the site of Guildhall, and there kept as porters. When they died, their effigies were set up in their place. This is Caxton's account; but there is another, which represents one of the giants as Gogmagog, and the other as a British giant who killed him, named Corinthus. However the fact may have been, the two giants have been the pride of London from time immemorial. On London Bridge, they welcomed Henry V. in 1415; they welcomed Henry VI. to London in 1422; and in 1554, Philip and Mary. In 1568, they stood by Temple Bar, when Elizabeth passed through the city gate. The old giants were burned in the great fire, and the new ones were constructed in 1706. They are 14 feet high, and occupy suitable pedestals in Guildhall. The ancient effigies, which were made of wicker-work and pasteboard, were carried through the streets in the Lord Mayor's Shows, and copies of the present giants were in the show of 1837. Formerly, other towns in England had their giants, and there are famous and some very large ones in several continental cities. The Antigonius of Antwerp is 40 feet high, and was formerly carried in the most solemn religious as well as civic processions. Gayant, the giant of Douai, is 22 feet high. There are also giants, and families of giants, at Lille, Malines, Brussels, &c., each connected with some popular tradition of their respective cities. The arms of Antwerp, a castle with severed heads, are connected with the legend of the giant who lived in the castle, and cut off the heads of those who failed to pay his exactions. Though it is now impossible to ascertain the facts, there can be little doubt that all these civic giants are exaggerated representatives of real persons and events.

GOGARI, a river rising in Nepal, about lat

27° 20' N., and long. 85° 46' E., joins the Coosy, an affluent of the Ganges, in lat. 25° 24' N., and long. 87° 16' E., after a course of 235 miles.

GOGO, a large town and a seaport of British India, in the presidency of Bombay, is situated on the west shore of the Gulf of Cambay, and has safe anchorage during the south-west monsoon, with smooth water and a muddy bottom. It is in lat. 21° 39' N., and long. 72° 15' E.

GOGOL, NIKOLAI, a Russian author of great and original genius, was born at the village of Wassiljewka, in the government of Poltova, in 1810. On finishing his studies, he went to St Petersburg, and solicited government employment, which was refused, on the ground, that 'he did not know Russian.' Shortly after, he proved that the officials were in the wrong by publishing a collection of novels and sketches, entitled *Večera na Khutorie* (Evenings at a Farmhouse). The first and most important of these tales contains a vivid picture of Cossack manners, enabling us, according to M. Sainte-Beuve, to comprehend the profound antipathies that have for ages characterised the relations of certain branches of the Slavic family to each other. Then come the 'King of the Gnomes,' the 'History of a Fool,' which is more a satire than a psychological study; and 'The House-keeping of Former Times,' a little masterpiece of its kind. The success of *Evenings at a Farmhouse* was immense, and Russian critics compared G.'s style to that of Washington Irving. It was followed by *Mirgorod*, a supplementary volume, of the same character, containing stories full of poetry, and exciting astonishment not less by the vigour and grasp of mind displayed in the delineation of character, than by the extraordinary skill with which the plots are formed and unravelled. G. now turned his attention to the dramatic art, and produced the *Revisor*, a comedy of brilliant genius, whose appearance on the stage excited quite a furor. The purpose of this piece was to expose the rooted abuses of the internal administration of Russian affairs. The Emperor Nicholas was the first to applaud its morality, and shewed his approbation by appointing the author professor of history in the university of St Petersburg. While holding this office, he published, in 1842, *Pokhozheniya Chichagova ili Mertvuiya Dushi* (Adventures of Chichagov, or Dead Souls), of which a bad translation appeared in English in 1854, under the title of *Home-life in Russia*. The aim of this novel was to extinguish serfdom by ridicule. Exhausted by his labours, G. sought permission to travel, and visited Italy, where he took up his residence. There, however, his opinions appear to have undergone a change. From being an ardent Russian liberal and reformer, he became an apologist of despotism, an apostasy which he lived to regret. After the commotions of 1848, he returned to Russia, and died at Moscow in 1851.

GOHILWAR, or GOHELWAD, a native principality, tributary at once to the Guicowar of Guzerat and to the British government, lies on the eastern coast of the peninsula of Kattywar, stretching in N. lat. from 20° 56' to 22° 3', and in E. long. from 71° 14' to 72° 13', and containing 3500 square miles, and 247,980 inhabitants. The chief's revenue is about 740,000 rupees a year, out of which he pays two tributes, about 80,000 rupees to the government of Bombay, and about 40,000 to the Guicowar.

GOIL, LOCH, a small but highly picturesque loch in Argyleshire, Scotland, is a branch of Loch Long (q. v.), and is six miles in length, and about one mile in breadth. Its shores are for the most part

wild and rugged; but the general character of the scenery is modified by extensive natural woods of hazel, which stretch along the shore. The mountains in the neighbourhood rise to the height of about 2500 feet. It may be visited by steamers from Glasgow.

GO'ITO, a small town in Lombardy, about 15 miles north-west from Mantua, occupies a beautiful though somewhat marshy position on the Mincio. This town, owing to its vicinity to the stronghold of Mantua, has been the field of various military operations. In 1630, it was carried by assault by the imperialists, who entered Mantua on the same night, and took it by surprise; during the war of the Spanish Succession in 1701, it was alternately captured by the allies and the imperialists; and in 1796 the French took it, but were expelled, after a brief tenure, by the Austrians. In 1814, a severe engagement took place at G. between the Austrian and Italian troops; and during the war of independence in 1848, it became the theatre of two further battles between the same powers, to which it owes its modern celebrity. Population inconsiderable.

GOITRE, an enlargement of the Thyroid Gland (q. v.), occupying the front of the neck, and sometimes of such a size as to project downwards over the breast, and even to admit of being thrown over the shoulder. Goitre is for the most part an endemic or local disease, being found in the mountainous regions of the Alps, Andes, and Himalaya, especially, it is said, where lime prevails largely as a geological formation. The proofs of goitre being connected with a calcareous impregnation of the drinking-water are rather strong, but perhaps not quite sufficient, especially as regards this country, though the chief seat of goitre in England, Derbyshire, is subject to this alleged cause. Goitre is met with endemically, to a slight extent, in various parts of Scotland; but on a very small scale indeed as compared with Switzerland, in which it is a very important deformity, especially when connected with Cretinism (q. v.). Goitre is of two kinds: the one due to increased development of the vessels of the gland, the other to the growth of Cysts (q. v.) in its substance. To these might perhaps be added a third, which is found in connection with functional disease of the heart, but which is perhaps only a variety of the vascular goitre. The usual treatment of goitre is by the administration of very minute doses of Iodine (q. v.) for a long time together. The use of this remedy is due to Coindet of Geneva, who recognised it as the principal source of the virtues of burned sponge, long of high repute in the treatment of goitre.

GOLCONDA, a fortress of the Nizam, situated seven miles to the north-west of his capital, Hyderabad, stands in lat. 17° 22' N., and in long. 78° 25' E. In its immediate neighbourhood are the ruins of an ancient city, once the metropolis of the kingdom of Golconda. The place itself is still strong; but its strength is seriously impaired through its being overtopped, within breaching-range, by the yet solid mausolea of its former sovereigns, which form a vast group at a distance of 600 yards. These tombs are dome-crowned structures of gray granite, each having its own mosque, and occupying the centre of its own elevated terrace. G. is proverbially famous for its diamonds; but, in truth, they are merely cut and polished here, being generally found at Parteall, near the southern frontier of the Nizam's dominions.

GOLD (symbol Au, atomic weight 99.6) has been known and regarded as the most precious of the metals from the earliest ages of the world, and has been universally employed as a medium of

exchange. Although the quantity of G. which is found, when compared with that of many other metals, is small, yet there are few parts of the globe in which it does not occur more or less abundantly.

In the native state, it occurs crystallised, the primary form being the cube, or in plates, ramifications, or nodules—popularly known as *nuggets*—which sometimes are of very considerable size. It is almost always alloyed with silver, and sometimes with tellurium, bismuth, lead, &c. It sometimes occurs in small quantity in metallic sulphides, as in galena, iron and copper pyrites.

The extraction of G. from the substances with which it is associated is effected more by mechanical than by chemical means. See below.

The following are its most important properties. In its compact state, it possesses a characteristic yellow colour and high metallic lustre, is nearly as soft as lead, and is the most malleable of all metals. It can be beaten into leaves of a thinness not exceeding $\frac{1}{1000}$ of an inch, or, according to some authors, $\frac{1}{2000}$ of an inch, through which light passes with a green tint; one grain may thus be distributed over 56 square inches of surface; and the ductility of the metal is so great, that the same quantity may be drawn out into 500 feet of wire. In its tenacity, it is inferior to iron, platinum, copper, and silver; but a wire whose diameter is 0.787 (or rather more than one-third) of a line (which is one-twelfth of an inch), will support a weight of about 150 lbs. It fuses at about 2016° , according to Daniell's pyrometer, and when in fusion, is of a bluish-green colour. It is scarcely at all volatile in the heat of the furnace, but by a powerful electric discharge, by the concentration of the sun's rays by a powerful burning-glass, or by the oxy-hydrogen jet, it is dispersed in purple vapours. G. has very little affinity for oxygen; it undergoes no change on exposure to the atmosphere, and is unaffected by hydrochloric, sulphuric, or nitric acid, or, in short, by any simple acid except selenic acid; nor do the alkalies affect it. It is, however, dissolved by any mixture which liberates chlorine, its usual solvent being *aqua regia*, which is generally prepared by mixing 1 part of nitric acid with 4 parts of hydrochloric acid. Hydrochloric acid to which biniodide of manganese has been added, acts equally well, the G. in these cases being converted into a chloride. This metal is one of the most perfect conductors both of heat and of electricity. When precipitated in a finely comminuted state, it is of a brown colour; but when suspended in water, and viewed by transmitted light, it appears purple. The specific gravity of this metal is less than that of platinum and iridium, ranging from 19.2 to 19.4, according as it is fused or hammered.

The alloys of G., or its combinations with other metals, are very numerous, those with copper and mercury being the most important. Copper and G. combine in all proportions without materially affecting the colour of the latter, except that it is somewhat redder. The density of the compound is less than that of G., but the hardness is greater, and it is more fusible. It is this alloy which is employed in our gold coinage, 11 parts of G. being combined with 1 of copper, without which the coin would not be sufficiently hard to stand the wear to which it is exposed. Hence British standard G. contains 8.33 per cent. of copper. In France, and in the United States, standard G. contains 10 per cent. of the latter metal. Jewellers alloy their G. with other metals, partly on economical grounds, and partly for the purpose of evolving special tints. Thus, red G. is obtained by combining 75 parts of fine G. with 25 of copper; green G., by combining 75 parts of fine G. with 25 of silver; dead-leaf

G., by combining 70 parts of fine G. with 30 of silver; water-green G., by combining 60 parts of fine G. with 40 of silver; blue G., by combining 75 parts of fine G. with 25 of iron.

Mercury and G. combine very readily, and yield a white alloy, termed an *amalgam*, which is used in gilding. In consequence of the readiness with which these metals unite even at ordinary temperatures, mercury is used for the extraction of gold.

As a general rule, the ductility of G. is much impaired by alloying other metals with it, while its hardness and sonorosity are increased.

Two oxides of G. are known—a protoxide, AuO , and a teroxide, AuO_3 . Neither of these oxides can be formed by the direct union of the elements, and both of them are reduced by heat. The protoxide is a dark-green or bluish-violet powder. It forms no definite salts. It is obtained by the decomposition of protochloride of G. with a solution of potash. The teroxide is a brown powder, which is reduced, not only by heat and light, but by many other reducing agents. It combines more readily with bases than with acids, and hence has been termed *auric acid*. We obtain it by mixing a solution of terchloride of G. with magnesia or carbonate of soda, and boiling.

Two chlorides of G. are known, corresponding to the oxides, viz., a protochloride, AuCl , and a terchloride, AuCl_3 . Of these, the latter is the most important: it is obtained by dissolving G. in aqua regia, and evaporating the solution to dryness, at a temperature not exceeding 300° , when we obtain this compound, as a deliquescent yellowish brown or reddish mass, which is soluble in water, alcohol, and ether, with which it forms orange-coloured solutions.

The chlorides of many of the organic bases form crystallisable double salts with the terchloride of G.; and these compounds are often employed to determine the combining power of the organic alkali.

Metallic G. in the form of a brown powder is thrown down from the solution of the terchloride by most reducing agents. This reducing power of protosulphate of iron is employed in the preparation of chemically pure gold.

A bisulphide of G. is obtained in the form of a black powder by passing a current of sulphuretted hydrogen through a cold solution of terchloride of gold. 'If finely divided gold be heated with sulphur in contact with carbonate of potash, a double sulphide of gold and potassium is formed; it resists a red heat, and is very soluble in water; this sulphur salt is used for gilding china, and produces the colour known as *Burgos lustre*.'—Miller's *Elements of Chemistry*, 2d edit. vol. ii. p. 74.

Fulminating G., a compound known to the alchemists, who (Basil Valentine, for example) formed solutions of terchloride of G., occurs as a green powder, when prepared by immersing teroxide of G. (or auric acid) in caustic ammonia. By modifying the mode of preparation, we obtain it of a brownish-yellow colour. From Dumas's analysis of the green powder, it seems to be represented by the formula $2\text{NH}_3, \text{AuO}_3$, the brownish-yellow powder having a more complicated formula. These powders detonate when rubbed, struck, or beaten, or when an electric spark is passed through them, with a loud sharp report and a faint light, and they yield nitrogen gas, ammonia, and water. None but professed chemists should attempt to prepare them, in consequence of their dangerous explosive character. On one occasion, a drachm of fulminating G. introduced into a bottle burst it as the stopper was being turned round, in consequence of small particles of it having adhered about the mouth, and both the

GOLD.

operator's eyes were destroyed by the projected fragments of glass.

The *Purple of Cassius* is an important gold compound. It derives its name from its having been first described by Andreas Cassius in 1685. See CASSIUS, PURPLE OF.

None of the salts of the oxides of G. are of sufficient importance to require notice in this article.

For the description of *Mosaic Gold*, see TIN.

GOLD was, in all probability, one of the earliest discovered of the metals. The fact of its being found very generally distributed over the surface of the earth, and that, too, in its simple metallic state, combined with its beautiful colour, and many valuable properties, would cause it very early to attract the attention of man. Accordingly, we learn that gold was used by the Hebrews, the Egyptians, and other ancient nations, for much the same purposes as it is at the present day.

Previous to the great Californian discovery in 1847, Europe was to a great extent supplied with G. from Mexico, Brazil, New Granada, Chili, and Peru in North and South America; a large quantity was also obtained from Asiatic Russia and the islands of the Indian Archipelago; the east and west coast of Africa furnished a less but still considerable quantity. All these countries still produce G., but their total yield, including Europe, is only about one-fourth that of California and Australia.

The most famous mines in Europe are those of Hungary and Transylvania, which produce annually about £300,000 worth of this metal. Piedmont and Spain are almost the only other European countries where G. is worked; but it is found in all districts where the rivers flow over primary rocks, though rarely in sufficient quantity to repay the expense of working it.

G. has been found in several parts of the British Islands. The most productive district yet discovered was that of Wicklow, in Ireland, where, towards the close of the last century, the stream-works were prosecuted for some time with considerable success. In Scotland, the Leadhills, on the borders of Dumfriesshire, as well as the Highlands of Perthshire, have at various times produced G.; so also have Cornwall and Devonshire in England, and, at the present time, a small quantity is being obtained from North Wales.

First among the celebrated gold discoveries of recent times, in point of date, though not in importance, come those of Eastern Siberia, where extensive auriferous tracts were discovered in the governments of Tomsk and Yeniseisk in 1842. The quantity obtained in these eastern regions raised the annual produce of the Russian empire to three, and ultimately to four millions sterling—more than triple its former yield. Concerning Russia, it may be well to remark that an examination of the auriferous deposits of the Ural Mountains led Sir Roderick Murchison, in 1844, on comparing their rocks with those brought home by Count Strzelecki from Australia, to predict the presence of G. on the latter continent. Subsequent discoveries, as is well known, have proved the accuracy of this conclusion in a very remarkable degree.

The rich gold region of California was discovered in September 1847. Mr Marshall, the contractor for a saw-mill on the estate of Captain Suter—a Swiss emigrant, settled on the banks of the Sacramento River—detected particles of G. in the sand of the mill-race, and on further examination, it was found that valuable deposits existed throughout the bed of the stream. Intelligence of the discovery soon reached the town of San Francisco, whose scanty population at once abandoned their usual occupations to join in the exciting search for

gold. The supply was soon found to be abundant over a large area; it occurred in the tributaries of the Sacramento as well as in the bed of the river itself, in old water-courses, and on the sides of the hills. Emigrants quickly poured in from all parts of the American continent, and ere long from Britain, Germany, and other European countries, till the population of San Francisco alone rose from under 200 in 1845 to 40,000 in 1858. At first, it was thought that the supply of G. from this region would soon fail, but it would appear by later researches to be far from being easily exhausted, as the supply, though now apparently decreasing, continued for several years at upwards of £13,000,000 per annum. See SAN FRANCISCO.

In 1851, before the excitement of the Californian discovery had time to subside, the world was startled by the announcement of another, or rather by a series of others, of not less importance, in Australia. It is a curious fact that not only Sir R. Murchison, as stated above, but also the Rev. W. B. Clarke, a native geologist, had pointed out the likelihood of G. being found in the eastern chain of the Australian mountains, several years before the value of the gold-fields near Bathurst was discovered by Mr Hargraves in April 1851. This discovery was no sooner made, however, than several other places in Bathurst and the adjoining counties were found to contain rich deposits; so that, before many months had passed, 6000 persons were employed at these *diggings*. In August of the same year, further discoveries of G. were made at Ballarat, in Victoria, which excelled in richness those of the Sydney district; and these, in turn, were soon surpassed by fresh discoveries in the Mount Alexander range. During the climax of the excitement created by the Victoria gold-fields, the number of diggers rose to upwards of 20,000, withdrawing for a time the great mass of the population from Melbourne and Geelong.

The modes of working adopted at the first start of the diggings were necessarily rude and wasteful; the fortunes of the gold-seekers, too, were of course very variable under such a system, many of them having made large profits—as much, in a few instances, as a thousand pounds and upwards in a single week—but many more met with nothing but disappointment. A more systematic plan of mining, however, has now been introduced, by which the auriferous deposits are more completely worked out, and the labour of the miners rendered less precarious. Notwithstanding this, the annual produce of the Australian colonies has now (1862) fallen to about £8,000,000, only two-thirds of what they produced a few years ago. In the International Exhibition of 1862 there was a gilded pyramid 10 feet square at the base and 45 feet high, representing the mass of gold exported from Victoria between the 1st October 1851 and the 1st October 1861. Its weight in solid gold would have been 26,162,432 ounces troy, which, taken roundly at £4 per ounce, gives its value as £104,649,728. The produce of California since the discovery of its gold-fields in 1847, up to the present time, may be estimated at about 37,500,000 ounces, and its value at £150,000,000.

Since the two great gold regions of California and Australia became known, three new ones of considerable promise have been discovered—one of them in British Columbia, the value of which was proved in 1858, although previously it was to some extent known to the Hudson's Bay Company; another is being successfully developed in Nova Scotia; and a third in the province of Otago, in New Zealand, the recent accounts from which are very encouraging. It would appear that there is a

great similarity between the general rock systems and auriferous deposits of this region and those of Australia. Before passing from the subject of recent gold-fields, it is worth noting that, a few years ago, Dr Livingstone the African traveller discovered G. near Tete on the Zambesi—a district which may be found to be rich in the precious metal, when more deliberately surveyed. Its position is remarkable as occurring in the centre of a coal-field.

The annual produce of G. in the whole world at the present time is somewhere between 30 and 40 millions sterling. Wherever G. is found, its origin can generally be traced to quartz veins in the primary or volcanic rocks, such as granite, gneiss, porphyry, clay-slate, or greenstone. As these rocks become decomposed by the action of the weather, portions of the auriferous veins are carried down by streams and floods, and so find their way into the deposits of sand, clay, and shingle in river-beds, and in the gullies and flats of hills. Many auriferous drifts are of great thickness, formed by long-continued wasting of the rocks of neighbouring hills, and therefore require mining to a considerable depth. G. for the most part is found in small grains, or scales, called gold-dust; some of it, however, in pieces, or *nuggets* of considerable size. The largest yet met with was found at Ballarat in 1858, called 'The Welcome,' it weighed 2166 oz., and its value was £8376, 10s. 10d. A good deal of the Mexican and European G. is obtained from auriferous pyrites; that is, the sulphuret of iron, copper, or arsenic, with the G. disseminated through it.

Nearly all the metals except G. are found, for the most part, at least, as ores chemically combined with oxygen, sulphur, or other substances; and they therefore require to be separated by chemical processes. Gold ores, if we may use the term, generally only require to be mechanically treated by the processes of crushing, stamping, grinding, and washing. The amalgamation process, however, is resorted to when the G. occurs in a state of fine division.

The crushing-mill consists of two large cast-iron cylinders or rollers revolving in opposite directions, which break the ore into small pieces as it passes through between them. To reduce it further, a stamping-mill is used with iron-shod piles of wood, or sometimes with stampers entirely of iron, wrought by an axle with projecting cams after the fashion of flint-mills and beeting-machines. To pulverise it still further, any form of grinding-mill is used, but the grinding surfaces should be of iron or of some hard rock like granite. The pounded ore is finally sifted and washed by machines, which vary in shape and mode of working, but they all consist essentially of sieves, to separate the larger from the smaller particles, and an inclined table or frame, across which a stream of water flows. The gold particles, on account of their greater specific gravity, remain at the head of the board, and the quartz and other impurities are carried forward and separated by the current.

By the above treatment, the greater part of the G. is extracted, but there still remain minute particles invisible to the naked eye mixed with the *gangue*; indeed, some auriferous soils contain all their G. in a state of extreme division. To recover this, the ore is partially concentrated by washing, and then an amalgam is made; that is, it is mixed with mercury, which has the power of seizing on and dissolving the gold particles, however minute. The mercury is afterwards distilled off in a cast-iron retort, leaving the G. nearly pure.

To give some idea of the quantity of G. used in the arts, of which very little can be recovered, it

may be stated that in the United Kingdom some 30,000 ounces in the shape of leaf gold, 10,000 ounces in the electroplate and other processes of gilding metals, and about the same quantity in gilding and making colours in the pottery districts, are annually consumed.

The quantity of G. poured into England during recent years has been immense. See GREAT BRITAIN. What has become of it all is often matter of surprise. Much has been sent to the mint, and much sent to foreign countries for their gold coinage. In France, Belgium, the Netherlands, and Italy, all large sums are now paid in G., instead of silver as formerly. That the continued influx of G. is gradually heightening prices in the United Kingdom is sufficiently obvious. The current price of standard gold is about £3, 17s. 6d.

GOLD-BEATER'S SKIN, a delicate membrane prepared from the large intestine of the ox, and used as a dressing for slight wounds, as the fabric for court-plaster, &c., but chiefly by gold-beaters. See GOLD-BEATING. The outer or peritoneal membrane is used for this purpose. The intestine is first subjected to a partial putrefaction, by which the adhesion of the membranes is sufficiently diminished to enable them to be separated; the separated membrane is then further cleaned from the adhering muscular fibres, dried, beaten, and pressed between paper, besides being treated with alum, isinglass, and white of egg, the object of which is to obtain the pure continuous membrane free from grease and impurities, without allowing the putrefactive processes to weaken it. A packet of 900 pieces of skin, each four inches square, is worth £8. They may be beaten continuously for several months with a twelve-pound hammer without material injury. The intestines of 500 oxen are required to furnish the 900 leaves that form one packet, or *mould*, as it is technically called. The manufacture is an extremely offensive one. Chlorine has been introduced both as a disinfectant and to assist in the separation of the membrane.

GOLD-BEATING, the process by which gold is extended to thin leaves used for gilding. The gold used for this purpose is usually alloyed with silver or copper, according to the colour required. See GOLD. For *deep gold*, an alloy containing about 1 part of copper to 20 of pure gold is used. As goldleaf is not sold by weight, but by superficial measure, and as increasing the quantity of alloy diminishes the malleability, there is but little temptation to use the baser metals as an adulteration.

The gold is first cast into oblong ingots about $\frac{1}{4}$ ths of an inch wide, and weighing two ounces. The ingot is flattened out into a ribbon of about $\frac{1}{16}$ th of an inch in thickness by passing it between polished steel rollers. This is annealed or softened by heat, and then cut into pieces of one inch square; 150 of these are placed between leaves of vellum, each piece of gold in the centre of a square vellum leaf, another placed above, and so on till the pile of 150 is formed. This pile is enclosed in a double-parchment case, and beaten with a 16-pound hammer. The elasticity of the packet considerably lightens the labour of beating, by causing the hammer to rebound with each blow.

The beating is continued until the inch-pieces are spread out to four-inch squares; they are then taken out, and cut into four pieces, and squares thus produced are now placed between *gold-beater's* skin instead of vellum, made into piles, and enclosed in a parchment case, and beaten as before, but with a lighter hammer. Another quartering; and beating produces 2400 leaves, having an area of about 190 times that of the ribbon, or a thickness

of about $\frac{1}{100}$ of an inch. An ounce of gold is thus extended to a surface of about 100 square feet. A still greater degree of thinness may be obtained, but not profitably. After the last beating, the leaves are taken up with wood pincers, placed on a cushion, blown out flat, and their ragged edges cut away, by which they are reduced to squares of $3\frac{1}{2}$ inches. Twenty-five of these are placed between the leaves of a paper-book, previously rubbed with red chalk, to prevent adhesion of the gold, and are sold in this form.

Attempts have been made to apply machinery to gold-beating, but though very ingenious, their application is very limited; most of the goldleaf is still beaten by hand.

GOLD COAST. See GUINEA.

GOLD-EYE (*Hyodon*), a genus of malacopterous fishes, inhabiting the lakes and rivers of North America; the type of a family, *Hyodontidae*, of which other members are found in tropical America and in Borneo. They are small fishes, much compressed like herrings, feed on insects like trouts, and like them are often taken by anglers with artificial flies. They have the mouth abundantly armed with teeth, having teeth far back on the palate as well as on the tongue and jaws.

GOLDFISH, or GOLDEN CARP (*Cyprinus auratus*), a fish of the same genus with the carp, a native of China, but now domesticated and naturalised in many parts of the world. It is said to have been originally confined to a lake near the mountain Tsien-king, in the province of The-kiang, in China; but this statement is of questionable accuracy. It has been long common in many of the fresh waters of China, and was introduced into England about the end of the 17th or beginning of the 18th century. On account of the brilliancy of its colours and the ease with which it is kept in glass globes or other vessels, in apartments, it soon became, and has continued to be, a general favourite. Its ordinary length is five or six inches, but it has been known to reach a foot. When young, it is of a blackish colour, but acquires its characteristic golden red as it advances to maturity, some individuals (*Silver-fish*) becoming rather of a silvery hue. Monstrosities of various kinds are frequent, particularly in the fins and eyes. The G. is now plentiful in some of the streams of Southern Europe, from which it is imported into Britain; but it also breeds in ponds in Britain, particularly in those into which hot water is poured from steam-engines, which sometimes swarm with its fry. In confinement, it may be fed with worms, insects, crumbs of bread, yolks of eggs dried and powdered, &c. Frequent changing of the water is advantageous, not only because of its being more fresh and better aerated, but because of the animalcules thus supplied for food.

GOLDLACE, a fabric formed by weaving silken threads that have been previously gilded. The peculiarity of this manufacture consists in the gilding of the silk in such a manner that it shall retain sufficient flexibility for weaving. A deep yellow or orange coloured silk is used for the purpose. The usual method of doing this, is by what is called 'fibre plating.' A rod of silver is gilded by simply pressing and burnishing leaves of gold upon it. This gilded silver is then drawn into very fine wire, so fine that one ounce of metal can be extended to the length of more than a mile. It is then flattened between polished steel rollers, and further extended so that a mile and a quarter weighs only one ounce; for the last drawing, the wire is passed through ruby dies. The film of gold upon this flattened wire is much thinner than beaten goldleaf,

and has frequently been quoted as an example of the divisibility of matter, as one inch of the highly gilded wire contains but the eighty-millionth part of an ounce of gold, or $\frac{1}{80,000,000}$ of an inch, which is a visible quantity exhibiting the colour and lustre of gold, contains but $\frac{1}{80,000,000}$ of an ounce, or one ounce of gold covers more than 100 miles of wire. This flattened gilded wire is then wound over the silk, so as to enclose it completely, and produce an apparently golden thread.

Other means of directly gilding the thread have been tried, and for some purposes are successful but none have yet been discovered which give the thread the same degree of lustre as the above, which was first practised in a ruder manner by the Hindus.

Mr Hock's method of fibre gilding is to pass the silk through a mucilaginous solution, and then receive it on a brass cylinder, over which it is closely rolled. Goldleaf is then laid upon this coil of gummed silk, and thus one side is coated. The other side is gilded by rolling it from the first on to a second cylinder in the opposite direction, thus the plain side falls outermost, and is then coated with goldleaf as before. This is rather cheaper than the fibre plated silk, and more flexible, but not so brilliant.

GOLD MINES. In England, the crown has *prima facie* the right to gold mines; but where the gold is found in other mines, the crown is entitled only to take the gold at a fixed price. In Scotland, by an ancient act of 1592, the owner of the ground can demand a feu thereof from the crown, on paying one-tenth of the produce.

GOLD OF PLEASURE (*Camelina*), a genus of plants of the natural order *Cruciferae*, having an erect calyx, small bright yellow flowers, and inflated pear-shaped or wedge-shaped pouches. The species are few. The common Gold of Pleasure (*C. sativa*), (Fr. *Cameline*, Germ. *Dotter*) is an annual plant 1½–3 feet high, with terminal racemes and pear-shaped pouches; the leaves smooth, bright green, entire or slightly toothed, the middle stem-leaves arrow-shaped and embracing the stem. Notwithstanding its high-sounding English name, the plant is of humble and homely appearance. It grows in fields and waste places in Europe and the north of Asia; it is not regarded as a true native of Britain, although often found in fields, particularly of flax, its seed being very commonly mingled with flaxseed imported from the continent. In many parts of Germany, Belgium, and the south of Europe, it is extensively cultivated for the sake of the abundant oil contained in its seeds. The seeds and the oil-cake made from them are also used for feeding cattle, although inferior to linseed, and to the oil-cake obtained from linseed. The oil, although sweet and pure at first, is very apt to become rancid, and is less valued than that of rapeseed or colza; the seeds of Gold of Pleasure are often mixed with rapeseed for the production of oil. The value of the plant in agriculture depends much on its adaptation to poor sandy soils, although it prefers those of a better quality; and on the briefness of its period of vegetation, adapting it for being sown after another crop has failed, or for being ploughed down as a green manure. The seed is sown either broadcast or in drills. The crop is cut or pulled when the pouches begin to turn yellow; but the readiness with which seed is scattered in the field, rendering the plant a weed for future years, is an objection to its cultivation. It is not much cultivated in any part of Britain. The stems are tough, fibrous, and durable, and are used for thatching and for making brooms; their fibre is even separated like that of flax, and made into very coarse cloth and packing-paper.

The seeds are used for emollient poultices, which allay pain, particularly in cutaneous diseases.

GO'LD'AU, formerly a small town of Switzerland, in the canton of Schwytz, was situated in a valley between Mount Rossberg on the north and Mount Rigi on the south, five miles north-west of the town of Schwytz, and is memorable for its destruction by one of the most stupendous and fatal landslips on record. The upper portion of the slope of the Rossberg, consisting of a layer of stone resting on light soil, had been loosened by continuous rains, which percolated under the rock, and in a measure washed the soil from beneath it. On the 2d September 1806, toward the evening, the outer layer of rock became completely detached, and rushed down the mountain in a south-western direction into the valley. In a few minutes not only G. but the neighbouring villages of Busingen and Rothen were overwhelmed in destruction, a part of the Lake of Lauwerz was filled up, and by the sudden overflowing of the water the land to the west of Seewen was devastated. Two churches, 111 dwelling-houses, 220 outhouses containing many cattle, and 400 men were buried in one moment. Only a few of the unhappy inhabitants who, at the moment of the landslip, were at some distance from the scene, were saved. A numerous company of travellers, who were on the point of commencing the ascent of Mount Rigi, were overtaken on the bridge of G. by the landslip, and perished. The valley is now a wild rocky waste, but grass and moes are gradually creeping over and veiling its more rugged features. On a height in this valley through which the highway leads from Arth to Schwytz, a chapel has been erected. Compare Zry's *G. und seine Umgegend* ('G. and its Neighbourhood,' Lucerne, 1829).

GO'LD'BERG, a manufacturing town of Prussia (of great antiquity), in the province of Silesia, is situated on an eminence on the banks of the Katsbach, 10 miles south-west of Liegnitz. It owes its origin and name to the gold-mines, which were worked here from the earliest times. At the commencement of the 12th c., they are said to have yielded 150 pounds of pure gold weekly. After the great victory won by the Mongol hordes near Liegnitz in 1241, in which 600 of the miners of G. perished, the town was taken by the conquerors. It also suffered greatly during the Thirty Years' War, and in 1813 was the scene of two engagements, the first between the French and Russians, and the second between the French and Prussians. G. is surrounded by double walls pierced by four gates; and is now celebrated for its manufactures of broadcloth, hosiery, and gloves, and for its fruit. Pop. 7040.

GOLDEN AGE. In the mythologies of most peoples and religions, there exists a tradition of a better time, when the earth was the common property of man, and produced spontaneously all things necessary for an enjoyable existence. The land flowed with milk and honey, beasts of prey lived peaceably with other animals, and man had not yet by selfishness, pride, and other vices and passions, fallen from a state of innocence. At the foundation of this legend lies the deeply-rooted opinion, that the world has degenerated with the progress of civilisation, and that mankind, while leading a simple, patriarchal life, were happier than at present. The Greeks and Romans placed this golden age under the rule of Saturn; and many of their poets—as, for example, Hesiod, in his *Works and Days*, Aratus, Ovid, and, above all, Virgil, in the first book of the *Georgics*—have turned this poetic *matériel* to admirable account, and defined the

gradual decadence of the world, as the silver, the brass, and the iron ages, holding out at the same time the consolatory hope that the pristine state of things will one day return.

GOLDEN BEETLE, the name popularly given to many of a genus of coleopterous insects, *Chrysomela*, and of a tribe or family, *Chrysomelinae* or *Chrysomelidae*, belonging to the tetramerous section of the order. The body is generally short and convex, the antennae are simple and wide apart at the base; some of the species are destitute of wings. Many are distinguished by great splendour of colour. None are of large size. The finest species are tropical, but some are found in Britain. Some of them, in the larva state, commit ravages on the produce of the field and garden.

GOLDEN BULL (Lat. *Bulla Aurea*, Ger. *Goldene Bulle*), was so called from the gold case in which the seal attached to it was enclosed. The imperial edict known in German history under this title, was issued by the Emperor Charles IV., mainly for the purpose of settling the law of imperial elections. Up to this time much uncertainty had prevailed as to the rights of the electoral body, claims having frequently been made by several members of the lay electoral families, and divisions having repeatedly arisen from this uncertainty; the effect of such divisions being to throw the decision for the most part into the hands of the pope. In order to obviate these inconveniences, the golden bull defines that one member only of each electoral house shall have a vote—viz., the representative of that house in right of primogeniture, and in case of his being a minor, the eldest of his uncles paternal. On the great question as to the dependence of the imperial office on the pope, and as to the right of the pope to examine and approve the imperial election, the golden bull is silent, although it declares the emperor competent to exercise jurisdiction in Germany from the moment of election. It invests the vicariate together with the government of the empire during the interregnum, in the Elector Palatine, and the Elector of Saxony; but it is remarkable that this only applies to Germany. On the vicariate of Italy, which was claimed by the popes, nothing is said. The golden bull also contains some provisions restraining the so-called *Faustrecht* (literally, 'fist-law'), or right of private redress. It was solemnly enacted in two successive diets at Nürnberg and Metz, in the year 1336, and original copies of it were furnished to each of the electors, and to the city of Frankfurt. The electoral constitution, as settled by this bull, was maintained almost unaltered till the extinction of the empire.

In Hungarian history there is a constitutional edict called by the same name. It was issued by Andrew II. in the early part of the 13th century. Without entering into details, it will be enough to say that the Golden Bull of Andrew II. changed the government of Hungary from an absolutism to an aristocratic monarchy, and that it contained till recent times the charter of the liberties of Hungary, or perhaps of the privileges of the noble class. See Schmidt's *Geschichte der Deutschen*, iii. 638.

GOLDEN-CRESTED WREN (*Regulus aurocapillus*), a very beautiful bird of the family *Sylviidae*, the smallest of British birds. Its entire length is scarcely three inches and a half. Notwithstanding its English name, it is not really a wren, but this name continues in popular use rather than *Regulus* and *Kinglet*, which have been proposed instead. The golden-crested wren is greenish-yellow on the upper parts, the cheeks and throat grayish-white; the crown feathers elongated, and forming a bright

yellow-crest. In its habits, it is intermediate between the warblers and the tits. It particularly affects fir-woods. It is not uncommon in Britain, from the most southern to the most northern parts; but many come also from more northern countries to spend the winter, and it is on record that, in October 1822, thousands were driven on the coast of Northumberland and Durham by a severe gale from the north-east. The nest of this bird is suspended from the outermost twigs of a branch of fir, some of them being interwoven with it.—Another species (*R. ignicapillus*), with more vividly red crest, is sometimes found in Britain, and species are found in Asia and North America.

GOLDEN-EYE. See GARROT.

GOLDEN-EYE FLY (*Hemerobius perla*, or *Chrysopa perla*), a neuropterous insect, common in Britain; pale green, with long threadlike antennae, long gauze-like wings, and brilliant golden eyes. Its flight is feeble. The length, from the tip of the antennae to the tip of the wings, is almost an inch and a half, but the insect without wings and antennae is not above one-third of this length. The female attaches her eggs, in groups of 12 or 16,

order; but at the close of the Spanish war of succession, the emperor, Charles VI., laid claim to it in virtue of his possession of the Netherlands, and taking with him the archives of the order, celebrated its inauguration with great magnificence at Vienna in 1713. Philip V. of Spain contested the claim of Charles; and the dispute, several times renewed, was at last tacitly adjusted by the introduction of the order in both countries. The insignia are a golden fleece hanging from a gold and blue enamelled flintstone emitting flames, and borne in its turn by a ray of fire. On the enamelled obverse is inscribed *Pretium laborum non vile*. The decoration was originally suspended from a chain of alternate firestones and rays, for which Charles V. allowed a red ribbon to be substituted, and the chain is now worn only by the Grand-Master. The Spanish decoration differs slightly from the Austrian. The costume consists of a long robe of deep red velvet, lined with white taffetas, and a long mantle of purple velvet lined with white satin, and richly trimmed with embroidery containing firestones and steels emitting flames and sparks. On the hem, which is of white satin, is embroidered in gold, *Je Fay emprie*. There is also a cap of purple velvet embroidered in gold, with a hood, and the shoes and stockings are red. In Austria, the emperor may now create any number of knights of the Golden Fleece from the old nobility; if Protestants, the pope's consent is required. In Spain, princes, grandees, and personages of peculiar merit are alone eligible.

GOLDEN LEGEND (Lat. *Aurea Legenda*), a celebrated collection of hagiology, which for a time enjoyed almost unexampled popularity, having passed through more than a hundred editions, and translations into almost all the European languages. It is the work of James de Voragine, also written 'Vragine' and 'Varagine,' who was born about the year 1230. He entered the Dominican order, and was elected, at a comparatively early age, provincial of the order in Lombardy in 1267. Towards the end of that century, he was elected Archbishop of Genoa; and by his ability, his moderation, and his exemplary life, he played a most influential part in the public affairs of his time, being called more than once into the councils of the popes themselves, in affairs of difficulty. The *Legenda* consists of 177 sections, each of which is devoted to a particular saint or festival, selected according to the order of the calendar. In its execution, the work, as may well be supposed from its age, is far from critical, but it is deserving of study as a literary monument of the period, and as illustrating the religious habits and views of the Christians of that time. It presents a very different phase of the medieval mind from that which is exhibited in the acute and severely philosophical lucubrations of the schools; but both must be read together, in order to make up the intellectual ideal of the time.

GOLDEN NUMBER for any year is the number of that year in the Metonic Cycle (q. v.), and as this cycle embraces 19 years, the golden numbers range from 1 to 19. The cycle of Meton came into general use soon after its discovery, and the number of each year in the Metonic cycle was ordered to be engraved in letters of gold on pillars of marble, hence the origin of the name. Since the introduction of the Gregorian calendar, the point from which the golden numbers are reckoned is 1 A.C., as in that year the new moon fell on the 1st of January; and as by Meton's law the new moon falls on the same day (1st of January) every 19th year from that time, we obtain the following rule for finding the golden number for any particular year,

Golden-eye Fly (*Chrysopa perla*)

(Copied from Morton's *Encyclopædia of Agriculture*):

a, cocoon; b, the same magnified; c, larva; d, the same magnified, and freed from adhering substances; e, perfect insect, on a branch to which its eggs are attached.

by long hairlike stalks, to leaves or twigs. They have been mistaken for fungi. The larvae are ferocious-looking little creatures, rough with long hairs, to which particles of lichen or bark become attached; they are called *aphis-lions*, and are very useful by the destruction of aphides, on which they feed. The pupa is enclosed in a white silken cocoon, from which the fly is liberated by a lid.

GOLDEN FLEECE, in Greek tradition, the fleece of the ram Chrysomallus, the recovery of which was the object of the Argonautic expedition. See ARGONAUTS. The Golden Fleece has given its name to a celebrated order of knighthood in Austria and Spain, founded by Philip III., Duke of Burgundy and the Netherlands, at Bruges, on the 10th January 1429, on the occasion of his marriage with Isabella, daughter of King John I. of Portugal. This order was instituted for the protection of the church, and the fleece was probably assumed for its emblem, as much from being the material of the staple manufacture of the Low Countries, as from its connection with heroic times. The founder made himself Grand-Master of the order, a dignity appointed to descend to his successors; and the number of knights, at first limited to 24, was subsequently increased. After the death of Charles V., the Burgundo-Spanish line of the House of Austria remained in possession of the

'Add 1 to the number of years, and divide by 19, the quotient gives the number of cycles and the remainder gives the golden number for that year; and if there be no remainder, then 19 is the golden number, and that year is the last of the cycle.' The golden number is used for determining the Epact (q. v.), and the time for holding Easter (q. v.).

GOLDEN-ROD (*Solidago*), a genus of plants of the natural order *Compositae*, sub-order *Corymbifera*, closely allied to *Aster*, but distinguished by the single-rowed pappus and tapering—not compressed—fruit. The species are natives chiefly of temperate climates, and are most numerous in North America. A few are European; only one is British, the COMMON G. (*S. Virgaurea*), a perennial plant of very variable size, as there is a small alpine variety (sometimes called *S. Cambrica*) only a few inches high, whilst the common variety, found in woods and thickets in most parts of Britain, is from one to four feet high. It has erect paniced crowded racemes of small yellow flowers. It is an ornamental plant, and is sometimes seen in gardens. It had at one time a great reputation as a vulnerary, whence the name *Solidago*, it is said, from Lat. *solidare*, to unite. The leaves of this and a fragrant North American species, *S. odora*, have been used as a substitute for tea. They are mildly astringent and tonic.

GOLDEN ROSE, a rose formed of wrought gold, and blessed with much solemnity by the pope in person on Mid-lent Sunday, which is called, from the first word of the festival, 'Letare Sunday.' The prayer of blessing contains a mystic allusion to our Lord as 'the flower of the field and the lily of the valleys.' The rose is anointed with balsam, fumed with incense, sprinkled with musk, and is then left upon the altar until the conclusion of the mass. Formerly, in the solemn papal procession of the day, the pope carried it in his hand. It is usually presented to some Catholic prince, whom the pope desires especially to honour, with an appropriate form of words. The origin of the ceremony is uncertain, but the most probable opinion as to its date is that of Martène and Du Cange, who fix it in the pontificate of Innocent IV. See Wetser's *Kirchen Lexicon*, vol. ix. 397.

GOLDEN RULE, a process in arithmetic, so called from the universality of its application. See PROPORTION.

GOLDFINCH (*Fringilla carduelis*, or *Carduelis elegans*), a pretty little bird of the family Fringillidae, a favourite cage-bird, on account of its soft and pleasing song, its intelligence, its liveliness, and the attachment which it forms for those who feed and caress it. The genus *Carduelis* is distinguished by a thick conical bill, without any bulging, attenuated and very sharp at the tip. There are two groups, and one British species of each—a group with gay plumage and more prolonged bill, of which the G. is the British representative, and another with darker plumage and shorter bill, represented by the Aberdevine (q. v.), or Siskin. The G. is about five inches in entire length; black, blood-red, yellow, and white are beautifully mingled in its plumage. The colours of the female are duller than those of the male. It is widely diffused throughout Europe, and is found in some parts of Asia. It is a common bird in Britain, more abundant in England than in Scotland, but somewhat local. It is to be seen in small flocks on open grounds, feeding on the seeds of thistles and other plants, and in the earlier parts of the season frequents gardens and orchards. Its nest is made in a tree, bush, or hedge, is remarkable for its extreme neatness, and is always lined

with the finest downy material that can be procured. The eggs are four or five in number, bluish white, with a few spots and lines of pale purple and brown. The G. is much employed by bird-catchers as a call-bird. It can be trained to the performance of many little tricks; that which, most of all, the trainers seem to prefer being the raising of water for itself as from a well, in a bucket the size of a thimble.—The AMERICAN G. (*F. or C. tristis*) is very similar to the European species, has very similar habits and song, and displays the same interesting liveliness and affectionateness in domestication. The nest is also of the same elegant structure. It is a common bird in most parts of North America.

GOLDO'NI, CARLO, the most celebrated writer of comedy among the Italians, was born at Venice in 1707, and received his first education at Rome. His father originally intended him for an actor, and fitted up a private theatre for his diversion at home, but the boy shewed no aptitude for histrionic performances, and in consequence he was sent to Pavia to study for the church. G., however, was still less fitted for being an ecclesiastic than an actor, and was finally expelled from college for writing scurrilous satires. In 1731, after his father's death, he was received as advocate; but finding the legal profession by no means lucrative, he relinquished its practice, and set about composing comic almanacs, which became highly popular. Several of his minor comedies were represented about this time, and attracted much public favour by their novelty as well as their real merit. In 1736 he espoused the daughter of a notary of Genoa, and subsequently went to Bologna, where, having obtained an introduction to Prince Lobkowitz, he was intrusted with the composition of an ode in honour of Maria Theresa, and with the organisation of the theatrical entertainments of the Austrian army. We next hear of him at Florence, working assiduously at comedies, which were, however, but an earnest of his best pieces. On his return to Venice he made very lucrative arrangements with the manager of the theatre of St Luke, and after a visit to Rome passed into France, and was appointed Italian master to the royal children, which situation allowed him to devote himself tranquilly to his literary occupations. In Paris he produced one of his most admired comedies, written in French, and entitled *Le Bourru bienfaisant* (The Benevolent Grumbler). It excited universal admiration, and drew forth a most eulogistic criticism from the pen of Voltaire. On the breaking out of the revolution, G. lost his pension, and died (January 1793) shortly before its restoration by decree of the Convention. The greater part of it was allowed to his widow, who likewise received the arrears due from the time of its cessation. G. has left 160 comedies of unequal merit. The larger part are inimitable representations of the events of daily life, under both their simplest and most complex aspect. One aim pervades steadily all G.'s compositions—the advancement and elevation of honourable sentiments and deeds, and the flagellation of the prevailing vices and follies of the day.

GOLDSCHMIDT, MADAME (JENNY LIND), a celebrated Swedish singer, was born at Stockholm, October 6, 1821. She was of humble parentage, and her musical gifts were first noticed by an actress, by whose influence she was admitted, at the age of nine, into the Conservatory of Stockholm, where she received lessons of Crolenius and Berg. She sang before the court with success, and at the age of 16 appeared in the rôle of Agatha, in *Der Freischütz*. Four years later, she went to Paris, to

receive lessons from Garcia. Her voice was now thought wanting in volume, and when she appeared at the Grand Opera two years later, her failure was so mortifying, that she is said to have resolved never again to sing in France. Returning to Stockholm, she was heard with enthusiasm in *Robert le Diable*, and at the instance of Meyerbeer was engaged at Berlin in 1845. After singing two years in Prussia, she visited Vienna, and other German cities, and made her *debut* in London in 1847, with a very marked success. Her return to Stockholm was greeted with an ovation, and the tickets to the opera in which she appeared were sold at auction. She returned to London in 1849, and won an immense triumph. The royal family and court were present at nearly every representation, and the receipts were often over £2000. The London season was followed by a concert tour in the provinces, with a similar success, and her great popularity was increased by the distribution of a large part of her receipts in charities. In 1850 she made an engagement with Mr P. T. Barnum of New York, for a concert tour in America, extending through the United States, British provinces, Mexico, and the West Indies. The receipts of this well-managed tour were 610,000 dollars, of which Mademoiselle Lind received 302,000 dollars. While in America, she was married to M. Otto Goldschmidt, the pianist who accompanied her, born at Hamburg 1828. They returned to Europe in 1852, and resided at Dresden after she had visited Stockholm, and expended £40,000 in endowing schools in her native country. Since this period Madame G. has sung only at concerts in England and on the continent, and on rare occasions. Her voice is a contralto of moderate range, but much power and expression. Her kind manners and abundant charities have contributed greatly to her popularity and success.

GOLDSINNY, or GOLDFINNY, a name given to certain small species of *Crenilabrus*, a genus of fishes of the Wrasse family (*Labridae*). They are rare on the British coasts, but are more plentiful on those of the north of Europe. They frequent rocky coasts, and are sometimes taken by anglers from the rocks. They receive their name from their prevalent yellow colour. Like the wrasses, they have a very elongated dorsal fin.

GOLDSMITH, OLIVER, was born in the village of Pallas, in the county of Longford, Ireland, 10th November 1728. His father, the Rev. Charles Goldsmith, a clergyman of the Established Church, held the living of Kilkenny West. At the age of six, G. was placed under the care of the village schoolmaster, when an attack of small-pox interrupted his studies. On his recovery, he attended school at various places. On the 11th June 1745, he entered Trinity College, Dublin, as a sizar; the expense of his education being defrayed by his uncle, the Rev. Thomas Contarine. At the university—where Burke was his contemporary—G. gave no evidence of the possession of talent, and becoming involved in some irregularity, quitted his studies in disgust. He lingered in Dublin till his funds were exhausted, then wandered on to Cork, where, he being in great distress, a handful of peas was given him by a girl at a wake, the flavour of which remained for ever sweet in his memory. By his brother Henry, he was brought back to college, where, on the 27th February 1749, he received the degree of B.A. His uncle was now anxious that his nephew should enter the church; but when he appeared before the bishop, he was rejected. His kind-hearted relative then gave him £50, and sent him to Dublin to study law; but G., being attracted to a gaming-table,

risked his entire capital, and of course lost it. Another sum was then raised, and he proceeded to Edinburgh to study medicine, where he remained 18 months, but did not take a degree. He then proceeded to the continent, hovered about Leyden for some time, haunting the gaming-tables with but indifferent success; and in February 1755, he left that city to travel on foot through Europe, scantily provided as to purse and wardrobe, but rich in his kindly nature and his wonder-working flute.

After taking his degree of B.M. at Padua or Louvain, G. returned to England in February 1756, when, by the assistance of Dr Sleigh, a fellow-student, he set up as a physician among the poor. He did not succeed in his profession, and he is represented as having become usher in the academy of Dr Milner at Peckham. During this period he supported himself by contributions to the *Monthly Review*. He became candidate for a medical appointment at Coromandel, but was rejected by the College of Surgeons. The clothes in which he appeared for examination had been procured on the security of Mr Griffiths, editor of the *Monthly Review*; and as G., urged by sharp distress, had pawned them, his publisher threatened him with the terrors of a jail. He had now reached the lowest depths of misery; but the dawn was about to break.

His first publication of note was an *Inquiry into the Present State of Politic Learning in Europe*, and was published in April 1759. In January 1760, Mr Newbery commenced the *Public Ledger*, to which G. contributed the celebrated *Chinese Letters*, afterwards republished under the title of *The Citizen of the World*. He also wrote a *Life of Beau Nash*, and a *History of England*, in a series of letters. On the 31st May 1761 he was introduced by Dr Percy to Dr Johnson, who, in his turn, introduced his new friend to the Literary Club. In December 1764, *The Traveller* appeared, and at once placed him in the front rank of English authors. Two years after this he published the *Vicar of Wakefield*, which has now charmed four generations. In rapid succession he produced his other works. The comedy of the *Good Natured Man*, in 1767; the *Roman History*, in 1768; and *The Deserted Village*—the sweetest of all his poems—in 1770. In 1773, his comedy of *She Stoops to Conquer* was produced at Covent Garden with great applause. His other works are—*Grecian History*, 1774; *Retaliation*, a poem, 1777; and *History of Animated Nature*, which he did not live to complete. Although now in receipt of large sums for his works, G. had not escaped from pecuniary embarrassment. He was extravagant, loved fine living and rich clothes, his charities were only bounded by his purse, and he haunted the gaming-table quite as frequently, and with as constant ill success, as of old. In March 1774, he came up to London, ill in body and harassed in mind, and took to bed on the 25th. With characteristic wilfulness and imprudence, he, contrary to the advice of his medical advisers, persisted in the use of James's Powders. He became rapidly worse, and Dr Turton said: 'Your pulse is in greater disorder than it should be from the degree of fever you have. Is your mind at ease?' 'No, it is not,' was the poet's reply, and the last words he uttered. He died on the 4th April, £2000 in debt, and more sincerely lamented than any literary man of his time. Old and infirm people sobbed on the stairs of his apartments, Johnson and Burke grieved and Reynolds, when he heard the news, laid down his pencil, and left his studio. He was buried in Temple Church, and a monument was erected to him in Westminster Abbey, bearing an epitaph by Dr Johnson.

G. was the most natural genius of his time. He did not possess Johnson's mass of intellect, nor Burke's passion and general force, but he wrote the finest poem, the most exquisite novel, and—with the exception perhaps of the *School for Scandal*—the most delightful comedy of the period. Blundering, impulsive, vain, and extravagant, clumsy in manner and undignified in presence, he was laughed at and ridiculed by his contemporaries; but with pen in hand, and in the solitude of his chamber, he was a match for any of them, and took the finest and kindest revenges. Than his style—in which, after all, lay his strength—nothing could be more natural, simple, and graceful. It is full of the most exquisite expressions, and the most cunning turns. Whatever he said, he said in the most graceful way. When he wrote nonsense, he wrote it so exquisitely that it is better often than other people's sense. Johnson, who, although he laughed at, yet loved and understood him, criticised him admirably in the remark: 'He is now writing a Natural History, and will make it as agreeable as a Persian tale.' The best life of Goldsmith is that by Forster, entitled *The Life and Times of Oliver Goldsmith* (Lond. 1854).

GOLDSMITHS' NOTES; the earliest form of bank-notes; so called because goldsmiths were the first bankers. See **BANK-NOTES**.

GOLF, or **GOLF**, a pastime almost peculiar to Scotland, derives its name from the club (Ger. *Kolbe*; Dutch, *Kolf*) with which it is played. It is uncertain when it was introduced into Scotland, but it appears to have been practised by all classes to a considerable extent in the reign of King James I. Charles I. was much attached to the game, and on his visit to Scotland in 1641, was engaged in it on Leith Links when intimation was given him of the rebellion in Ireland, whereupon he threw down his club, and returned in great agitation to Holyroodhouse. The Duke of York, afterwards James II., also delighted in the game; and in our own day, the Prince of Wales occasionally practises it.

Until late years, golf was entirely confined to Scotland, where it still maintains its celebrity as a national recreation; but latterly it has been established south of the Tweed, as well as in many of the British colonies. It is played on what are called in Scotland *links* (Eng. *downs*), that is, tracts of sandy soil covered with short grass, which occur frequently along the east coast of Scotland. St Andrews and Leven in Fife, Prestwick in Ayrshire, Musselburgh in Mid Lothian, North Berwick and Gullane in East Lothian, Carnoustie and Montrose in Forfarshire, and Aberdeen, are examples of admirably suited links, as the ground is diversified by knolls, sand-pits, and other *hazards* (as they are termed in golfing phraseology), the avoiding of which is one of the most important points of the game.

A series of small round holes, about four inches in diameter, and several inches in depth, are cut in the turf, at distances of from one to four or five hundred yards from each other, according to the nature of the ground, so as to form a circuit or *round*. The rival players are either two in number, which is the simplest arrangement, or four (two against two), in which case the two partners strike the ball on their side alternately. The balls, weighing about two ounces, are made of gutta-percha, and painted white so as to be readily seen.

An ordinary golf-club consists of two parts spliced together—namely, the shaft and head: the shaft is usually made of hickory, or lance-wood; the handle covered with leather; the head (heavily

weighted with lead behind, and faced with horn) of well-seasoned apple-tree or thorn. Every player has a set of clubs, differing in length and shape to suit the distance to be driven, and the position of the ball; for (except in striking off from a hole, when the ball may be *tee'd*—i.e., placed advantageously on a little heap of sand, called a *tee*) it is a rule that the ball must be struck as it happens to lie. Some positions of the ball require a club with

Club Heads;

- 1, play-club; 2, putter; 3, spoon; 4, sand-iron; 5, cleft;
- 6, niblick or track-iron.

an iron head. The usual complement of clubs is six; but those who refine on the gradation of implements use as many as ten, which are technically distinguished as the *play-club*, *long-spoon*, *mid-spoon*, *short-spoon*, *baffing-spoon*, *driving-putter*, *putter*, *sand-iron*, *cleft*, and *niblick* or *track-iron*—the last three have iron heads, the others are of wood. Every player is usually provided with an attendant, called a *caddy*, who carries his clubs and 'tees' his balls.

The object of the game is, starting from the first hole, to drive the ball into the next hole with as few strokes as possible; and so on round the course. The player (or pair of players) whose ball is holed in the fewest strokes has gained that hole; and the match is usually decided by the greatest number of holes gained in one or more rounds; sometimes it is made to depend on the aggregate number of strokes taken to 'hole' one or more rounds.

To play the game of golf well requires long practice, and very few attain to great excellence who have not played from their youth. But any one may in a year or two learn to play tolerably, so as to take great pleasure in the game; and for all who have once entered upon it, it possesses no ordinary fascination. It has this advantage over many other outdoor games, that it is suited both for old and young. The strong and energetic find scope for their energy in driving long balls (crack-players will drive a ball above 200 yards); but the more important points of the game—an exact eye, a steady and measured stroke for the short distances, and skill in avoiding hazards—are called forth in all cases. Along with the muscular exercise required by the actual play, there is a mixture of walking which particularly suits those whose

pursuits are sedentary—walking, too, on a breezy common, and under circumstances which make it far more beneficial than an ordinary 'constitutional.'

Putting.

In the accompanying illustration, the method of holding the club, when putting the ball into the hole, is shewn.

Golf Associations are numerous in Scotland, and in many instances the members wear a uniform when playing. Many professional players make their livelihood by golf, and are always ready to instruct beginners in the art, or to play matches with amateurs.

The rules laid down by the St Andrews Royal and Ancient Union Club are those that govern nearly all the other associations, and may be found in *Chambers's Information for the People*, No. 96.

GOLFO DULCE, in English, *Sweet or Fresh Gulf*, lies in the state of Guatemala, in Central America, measuring 26 miles by 11, and having an average depth of 6 or 8 fathoms. It communicates with the outer sea, here known as the Gulf of Honduras, by a narrow strait or stream called the Rio Dulce.

GO'LGOTHA, a Hebrew word signifying a 'skull,' and so it is interpreted by Luke; but by the other three evangelists, 'the place of a skull.' The Latin equivalent is *Calvaria*, 'a bare skull.' This place, the scene of the crucifixion of Christ, was situated without the gates of Jerusalem, on the eastern side of the city, although the common opinion handed down from the middle ages fixes it in the north-west (see CALVARY). It was probably the ordinary spot of execution, though this is to be inferred rather from the fact that, in the eyes of the Roman officers of justice, Christ was simply a common criminal, than from any supposed connection between the word 'skull' and a place of execution; G. receiving its name in all likelihood from its round skull-like form. A church was built over the spot in the 4th c. by Constantine. What is now called the 'Church of the Holy Sepulchre' to the north-west of Jerusalem, but within the walls of the city, has manifestly no claim whatever to be considered the building erected by Constantine; but while recent biblical scholars and travellers generally have assumed that the scene of our Saviour's crucifixion

and sepulture is not ascertainable, a writer in Smith's *Dictionary of the Bible* offers strong reasons for believing that the present mosque of Omar, called by the Mohammedans 'The Dome of the Rock,' occupies the site of the sacred Golgotha.

GOLI'ATH. See GATH.

GOLIATH BEETLE (*Goliathus*), a genus of tropical coleopterous insects, of the section *Pentamer*,

Goliath Beetle (*Goliathus nigrus*).

and remarkable for the large size of some of the species, particularly the African ones. They are also, in respect of their colours, splendid insects. Little is known of their habits.

GO'LLNITZ, a small town in the north of Hungary, in the county of Zips, is situated on the left bank of a river of the same name, a feeder of the Hernad, 17 miles south-west of Eperies. It has important iron and copper mines, and manufactures of wire and cutlery. Pop. 5200.

GO'LLNOW, a small manufacturing town of Prussia, in the province of Pomerania, is situated on the right bank of the Ihna, 15 miles north-east of Stettin. It was formerly a Hanse-town, and is surrounded by walls, and defended by two forts. The manufactures are woollen cloth, ribbons, paper, and tobacco; there are also copper-works. Pop. 5207.

GOLOMY'NKA (*Comephorus Baikalensis*), a remarkable fish, found only in Lake Baikal, the only known species of its genus, which belongs to the goby family. It is about a foot long, is destitute of scales, and is very soft, its whole substance abounding in oil, which is obtained from it by pressure. It is never eaten.

GOLOSSES (formerly called galosches), from *Galoché*, a word through the French, from *Galocha*, the Spanish for a patten, clog, or wooden shoe. The French applied the term at first to shoes partly of leather and wood, the soles being wood, and the uppers of leather. The term was introduced to this country as a cordwainer's technicality, to signify a method of repairing old boots and shoes by putting a narrow strip of leather above the sole so as to surround the lower part of the upper leather. It was also adopted by the patten and clog makers to distinguish what were also called French clogs from ordinary clogs and pattens. Clogs were mere soles of wood with straps across the instep to keep them on; pattens were the same, with iron rings to raise them from the ground; but the galosches were wooden soles, usually with a joint at the part where the tread of the foot came, and with upper leathers like very low shoes.

Now, however, these clogs, pattens, and galosches

GOLPE—GOMBROON.

have completely passed away except in some rural districts which are almost inaccessible to modern inventions: the American goloshes have entirely superseded them. These are manufactured of vulcanised India rubber or caoutchouc, and are now made in the most elegant forms; being elastic, they are worn as overshoes in wet weather, and are an excellent protection to the feet. At first, India-rubber goloshes were all imported from the states of America, and in 1856 the value of the imports of this article reached the enormous sum of £75,442; now, however, vast numbers are made in this country, chiefly by the North British Rubber Company (Limited), whose works are called the Castle Mills, in Edinburgh. In this vast building, when in full work, 10,500 pairs of goloshes are daily made; and so perfect is the arrangement of the manufacture, which is chiefly conducted by Americans, that in a few hours large masses of the raw material are converted into overshoes, boots, sheets, bands, rings, washers, and a great variety of other useful articles. The process of making goloshes consists, first, in preparing the raw material; secondly, kneading it up with certain chemical materials, the composition of which is carefully concealed by the manufacturers, but the principal constituent is sulphur; thirdly, rolling it out into sheets of the thickness required; and lastly, fashioning it into goloshes.

In the first operation, the rubber is first placed in warm water violently agitated; this softens it, and removes a considerable quantity of dirt and other impurities; it is then put into a machine, which tears it into very small pieces in water, thus also removing much impurity. Still warm, and somewhat adhesive in consequence, the small fragments into which the rubber has been torn are spread out into a thick sheet, which travels between two rollers about an inch apart; these press the fragments together, and they adhere slightly in the form of a thick blanket, about two feet wide, and from four to six feet in length. The slight adhesion of the very irregularly shaped morsels of rubber renders this flattened sheet very porous, and in this state it is hung in the drying-room, to remove the moisture with which it is loaded. These sheets are next passed between large cylindrical iron rollers heated with steam internally, which compress the material into thin soft sheets. The chemical materials are now spread equally over the sheet, and it is folded up and kneaded so as to work the vulcanising materials and rubber well together. This kneading process is performed by passing it several times through the hot rollers, folding it after each rolling into a dough-like mass. When this operation is completed, it is finally rolled out into thin sheets several yards in length, which are reeled off on cold rollers at some distance, so as to allow cooling, and it is then ready for the *uppers* of the commonest kind of goloshes, which are unlined; but the better sorts are lined with cotton cloth of different colours, and sometimes with other materials; the lining is effected by passing the piece of cloth through the rollers simultaneously with the rubber in the last process, and a firm adhesion of the two is effected by the heat and pressure.

Another machine has rollers so modelled that it produces a sheet thick enough for the soles, and on one surface the roughening is made by engraved lines crossing each other, to prevent the sole from slipping in wet weather. An ingenious arrangement of this machine forms about two inches of each side of the sheet which passes through it a little thicker than the middle portion, and this serves for the raised heels. After the sheets for the *uppers* and *heels* have been cooled and reeled off,

they pass through the cutting machines. In these are fitted sharp cutting moulds of different sizes and shapes: some cut out the inside linings and the outside uppers for fronts and heel-steppings; whilst others with great nicety cut the heeled soles out.

These various parts are now taken to the makers, who are usually females; and the last—which is now made of cast iron as an improvement on the wooden ones formerly in use—is rapidly covered over with the various parts, beginning with the lining and insole, the edges of which are cemented with a composition probably containing liquefied India rubber or gutta-percha; but its real composition is another secret of the manufacture, and is held to be a very important one: it produces an instantaneous and firm adhesion. The outer parts and the sole are fitted on with equal facility, and the workwoman then runs a wheel-tool round the edges and other parts, to produce the representation of seam marks. In this way a pair of shoes is produced in little more than five minutes. They are next coated with a varnish, which gives them a highly polished appearance; and when the varnish has hardened, which it does very quickly, they are transferred to the vulcanising ovens or chambers, in which, for some time, they are submitted to a high degree of heat, which produces a chemical union between the caoutchouc and the other materials which were mixed in with it at the beginning of the operations. When taken from the oven, they are removed to the packing-room, and are sent in boxes to all parts of the kingdom, and to most parts of Europe, especially Germany, where they are very extensively worn. The North British Rubber Company produced nearly three million pairs of overshoes and boots in 1861.

GOLPE, in Heraldry, a Roundel purpure. It is sometimes called a *Wound*. See **ROUNDEL**.

GOMARISTS, or **CONTRA-REMONSTRANTS**, the name by which the opponents of the doctrines of Arminius (q. v.), the founder of the Dutch Remonstrants, were designated. The party received this appellation from its leader, Francis Gomar. This theologian was born at Bruges, 30th January 1563, studied at the universities of Strasburg, Heidelberg, Oxford, and Cambridge, in the last-mentioned of which he took his degree of B.D. in 1584. In 1594, he was appointed professor of divinity at Leyden, and signalled himself by his vehement antipathy to the views of his colleague, Arminius. In the disputation between the Armenians and Calvinists, held at the Hague in 1608, his zeal was very conspicuous; and at the synod of Dort in 1618, he was mainly instrumental in securing the expulsion of the Arminians from the Reformed Church. He died at Gröningen in 1641. An edition of his works was published at Amsterdam in 1645. G., though stiff and bigoted in the last degree, and more Calvinistic than Calvin himself, was a man of various and extensive learning.

GOMBROON, called also **BENDER** or **BUNDER** **ABBAS**, a town and seaport of Persia, stands at the mouth of the Persian Gulf, in the Strait of Ormuz, and opposite the island of that name. Bender Abbas owed its name and importance to Shah Abbās, who, assisted by the English, drove the Portuguese in 1622 from Ormuz, or Hormuz, then a flourishing commercial town on the island of the same name, ruined the seaport, and transferred its commerce to Gombroon. For some time G. prospered abundantly, French, Dutch, and English factories were erected here, and the population rose to about 30,000. A dispute among the natives, however, resulted in the destruction of the European factories and houses, and only the remains of these now exist. Trade then

almost entirely forsook G.; it is now inhabited by only about 4000 Arabs under a sheikh, who is subject to the sultan of Muscat, in Arabia. The town is surrounded by a mud wall; its streets are narrow and dirty.

GOMERA, one of the Canary Islands (q. v.).

GOMO'ERAH. See SODOM AND GOMORRAH.

GOMUTO, ARENG, or EJOO PALM (*Arenga saccharifera*, or *Saguerus Rumphii*), an important palm which grows in Cochin China and in the islands of the Indian Archipelago, particularly in moist and shady ravines. The stem is 20–30 feet high; the leaves 15–25 feet long, pinnated. The flowers are in bunches 6–10 feet long; the fruit is a yellowish-brown, three-seeded berry, of the size of a small apple, and extremely acid. The stem, when young, is entirely covered with sheaths of fallen leaves, and black horse-hairlike fibres, which issue in great abundance from their margins; but as the tree increases in age, these drop off, leaving an elegant naked columnar stem. The strongest of the fibres, resembling porcupine quills in thickness, are used in Sumatra as styles for writing on the leaves of other palms. But the finer fibres are by far the most valuable; they are well known in eastern commerce as Gomuto or Ejoo fibre, and are much used for making strong cordage, particularly for the cables and standing-rigging of ships, European as well as native. Want of pliancy renders them less fit for running-rigging, and for many other purposes. They need no preparation but spinning or twisting. No ropes of vegetable fibre are so imperishable, when often wet, as those made of Gomuto fibre. At the base of the leaves of the Gomuto palm there is a fine woolly material, called *baru*, which is much employed in caulking ships and stuffing cushions. The stem contains a large quantity, 150–200 lbs., of a kind of sago. The saccharine sap, obtained in great abundance by cutting the spadices of the flowers, is a delicious beverage, and by fermentation yields an intoxicating palm wine (*neroo*), from which a spirituous liquor called *brum* is made.

GONAIVES, a seaport of Hayti, with an excellent harbour, stands on a bay of its own name, which deeply indents the west coast of the island. It is 65 miles to the north-west of *Port Republicain*, formerly *Port au Prince*, the capital.

GO'NDAR, a city of Abyssinia, capital of the kingdom of Gondar or Amhara, is situated in lat. 12° 36' N., and long. 37° 29' E., on an insulated hill at an elevation of 7420 feet above sea level, and is 30 miles distant from the northern shore of Lake Dembea or Izana (see ABYSSINIA). G. is the residence of the emperor or *Negus*, whose authority is now merely nominal, and at one time had from 60 to 100 churches and about 50,000 inhabitants; but since the dismemberment of the kingdom, it has greatly declined, and its extent or population cannot now be accurately stated. It is poorly and irregularly built, and resembles a wood rather than a city, on account of the number of trees surrounding the houses. The palace of the emperor, a square stone structure flanked with towers, is the most important building. There are no shops or bazaars, all the articles for sale being exposed on mats in the market-place. G. has manufactures of fire-arms, sword-blades, knives, scissors, razors, shields, pottery, &c.; and a considerable transit trade between Massuah on the Red Sea and the south of Abyssinia, in slaves, musk, wax, ivory, coffee, honey, &c. The mean temperature of G., as observed by Rüppell during the seven months from October to April inclusive, was 69°, and the lowest temperature during that time was 53·09°. A great quantity of rain falls here.

GONDOLA (Italian), a long narrow boat (averaging 30 feet by 4) used chiefly on the canals of Venice. The prow and stern taper to a point, and curve out of the water to a height of at least 5 feet.

Venetian Gondola.

In the centre there is a curtained chamber for the occupants: the boat is propelled by means of oars or poles by one, two, or occasionally four men. The rowers stand as they row, and wear the livery of the family to which the gondola belongs.

The term gondola is also applied to passage-boats having six or eight oars, used in other parts of Italy.

GONDWANA, the land of the Gonda, is a hilly tract of Hindustan, lying between 19° 50' and 24° 30', and in E. long. between 77° 38' and 87° 20'. It occupies a somewhat central position, sending its drainage at once northward into the Jumna, eastward through the Mahanadi into the Bay of Bengal, and westward through the Tapti and the Nerbudda into the Arabian Sea—the watershed in some places attaining an elevation of 5000 feet. So isolated a locality, besides being in itself unfavourable to civilisation, is rendered still more so by the extreme barbarism of the inhabitants, who are regarded, with some appearance of probability, as the genuine aborigines of India. Certain it is, that the country has never really formed a part of any of the great empires in the east.

GO'NFALON (Ital. *gonfalone*), an ensign or standard; in virtue of bearing which, the chief magistrates in many of the Italian cities were known as *gonfalonieri*.

GONG, an Indian instrument of percussion, made of a mixture of metals (78 to 80 parts of copper, and 22 to 20 parts of tin), and shaped into a basin-like form, flat and large, with a rim of a few inches deep. The sound of the G. is produced by striking it, while hung by the rim, with a wooden mallet, which puts the metal into an extraordinary state of vibration, and produces a very loud piercing sound.

GONGORA, LUIS Y. ARGOTE, a Spanish poet, was born at Cordova, 11th July 1561; studied law at the university of Salamanca, where he composed the greater part of his erotic poems, romances, and satires. At the age of 45, he took orders, and obtained a small prebend in the cathedral of Cordova. He was afterwards appointed chaplain to Philip III., and died in his native city 24th May 1627. G.'s poetic career divides itself into two periods. In his first or youthful period, he yielded himself up entirely to the natural tendencies of his genius, and to the spirit of the nation. His lyrics and romances of this period are in the old

genuine Spanish style; and in respect to their caustic satire and burlesque wit, are among the most admirable specimens of the class of poems to which they belong. G., however, wished to outdo all his predecessors, and to furnish something wholly new and unheard of; the result of which unfortunate ambition was the introduction of a new poetic phraseology, called the *estilo culto*, or the 'cultivated style.' From this point the second period in G.'s literary career dates. To popularise the *estilo culto*, he wrote his *Polifemo*, *Soledades*, and the *Fables of Pyramus and Thisbe*, productions of the most pedantic and tasteless description, poor in invention and thought, but rich in high-sounding pompous phrases, and overloaded with absurd imagery, and mythological allusions, expressed in language of studied obscurity. In this way he became the founder of a new school, the *Gongoristas*, or *Oulioristas*, who even surpassed their master in the depravity of their literary tastes. The most complete edition of G.'s works is that by Gonzalo de Florez y Córdoba (Mad. 1633). Some of his romances have been translated into German by J. G. Jacobi (Halle, 1767).

GONIATITES, a genus of fossil cephalopodous mollusca, belonging to the same family as the ammonites. The genus is characterised by the structure of the septa, which are lobed, but without lateral denticulations, as in ammonites; they consequently exhibit, in a section, a continuous undulating line. Some forms with slightly waved septa approach very near to the nautilus, from which, however, they are at once separated, by the position of the small and delicate siphuncle, which is on the dorsal or external side of the shell. The lines of growth on the external surface have a sigmoid direction. The siphonal portion is shorter than the sides, forming a sinus at the back, as in the nautilus. The last chamber, the one tenanted by the animal, occupies a whole whorl, and has besides a considerable lateral expansion. The shells are small, seldom exceeding six inches in diameter.

This genus is confined to the Palæozoic strata: upwards of 150 species have been described from the Devonian, Carboniferous, and Triassic measures.

GONIDIA (Gr. *gonē*, generation, and *eidōs*, an appearance), small green bodies which in some cryptogamous plants serve the purpose of reproduction, but apparently after a manner analogous to that of bulbils in phanerogamous plants, rather than by true fructification. It is not, however, certain that the bodies called gonidia in different classes of cryptogamous plants are all of exactly the same nature. The gonidia of Lichens (q. v.) are found in layers in the interior of the thallus. In some of the lowest vegetable organisms, as *Desmidiaceæ*, the gonidia are formed by the *endochrome* or contents of the cell breaking up into granules, sometimes invested with cilia, and moving as zoospores, at first within the cavity of the cell in which they are formed, and afterwards without it.

GONIO'METER, an instrument for measuring the angles of crystals. The simplest instrument is that invented by Carangeau, which consists of two brass rulers turning on a common centre, between which the crystal is so placed that its faces coincide with the edges of the rulers, and the angle is measured on a graduated arc. For large crystals this is sufficiently accurate, but as many minerals are found crystallised only in small crystals, and as small crystals of any mineral are generally the most perfect, an instrument capable of measuring more exactly was required. The one generally in use is the reflecting goniometer invented by Wollaston, and improved by Nauman. This is a

more complicated instrument, yet easy of application, and it will measure very small crystals with certainty to within a single minute (1'). The angle is measured by the reflection of the rays of light from the surface of the different faces of the crystal.

GONORRHOEA (*gonos*, progeny or seed, and *rheō*, I flow), a name originally applied almost indiscriminately to all discharges from the genital passages in both sexes, but especially in the male. In the course of usage, the term has been almost entirely restricted to the designation of one particular kind of discharge, which, from its connection with a contagious poison, was originally called, in strict nosological language, *G. virulenta*. This form of the disease is usually caused by the direct communication of sound persons with those already affected; and accordingly G. is one of the numerous penalties attending an indiscriminate and impure intercourse of the sexes. See SYPHILIS. G. is a very acute and painful form of disease; it is liable, however, to leave its traces in the more chronic form of gleet, which may last for a considerable time, and may give rise to alarm from being mistaken for other disorders. A description of the symptoms and cure of G. would of course be out of place in a work like the present; but we may avail ourselves of this opportunity to warn the victims of G., and the allied disorders, against consulting any but medical men of the highest standing, and of undoubted character. An unworthy class of practitioners exists, who live chiefly by inveighing and frightening the unwary, and who not unfrequently extort vast sums of money by threats of exposure of what is communicated to them in confidence. The advertisements of these men are an offence to decency, and should act as beacons to the public, rather than as they are intended.

GONVILLE AND CAIUS COLLEGE, CAMBRIDGE, was originally founded in 1348 by Edmund Gonville, son of Sir Nicholas Gonville, rector of Terrington, in Norfolk, and endowed for a master and three fellows. In 1353, William Bateman, Bishop of Norwich, whom Gonville had appointed his executor, changed the situation of the college to its present site, and altered the name to the 'Hall of the Annunciation of Blessed Mary the Virgin.' In 1558, Dr Caius obtained a royal charter, founding the college for the third time, and altering the name to that which it now bears. By the present statutes, the college consists of a master, thirty fellows, and thirty-six scholars. There are also at this college four studentships in medicine, founded by Christopher Tancred, each of the annual value of £113.

GONZA'GA, a town of Northern Italy, 14 miles south-south-east of Mantua, with 14,580 inhabitants, is the chief town of the district of Gonzaga, of which the population is 24,841. The town was formerly fortified and protected by a strong castle, and some assert that the family of Gonzaga, who ruled for four centuries over Mantua, originated in this locality. The territory surrounding G. is a well-watered and fertile plain.

GONZAGA, HOUSE OF, a princely family of German origin, from which sprang a long line of sovereign Dukes of Mantua and Montferrat. The sway of this race over Mantua extended over a period exceeding three centuries, and many of its members were magnificent promoters and cultivators of arts, science, and literature. Wielding originally in the state the vast civic influence which in so many instances we find exercised by families of weight in the history of Italy, the Gonzagas gradually monopolised all the chief posts of command,

both civil and military; and finally, in 1432, were invested with the title and jurisdiction of hereditary marquises, and in 1530 with that of dukes or sovereigns of the state. After their elevation to ducal dignity, they continued to own the feudal supremacy of the empire, and were the faithful champions of the imperial interests in their policy with other states. The House of G., and that of the Visconti Dukes of Milan, were perpetually at war. The most illustrious personages of this race were GIOVANNI FRANCESCO (1407—1444), in whose favour Mantua was created a marquisate by the Emperor Sigismund, in return for his services to the empire.—GIAN FRANCESCO (1484—1519), who defeated Charles VIII. of France at the battle of Fornovo, on the banks of the Taro, 1495, when G. left 3500 troops on the field, and Charles was forced to a hasty retreat. G. also took part in the engagement of Atella, 1496, which led to the capitulation of the French forces. His son, FREDERICK II. (1519—1540), in recognition of the services he rendered the imperial forces in their contest with France, was invested by the Emperor Charles V. with the ducal dignity in 1530, and also obtained the marquisate of Montferrat in 1536. During the reign of this prince, the court of Mantua was one of the most magnificent and gay of Europe.—GUGLIELMO (1550—1587), the son of Frederick, was humpbacked, but proved a wise and enlightened ruler; his secretary was Bernardo Tasso, father of the poet.—VINCENTO (1587—1612), son of Guglielmo, was the warm friend and patron of Tasso, and succeeded in obtaining the poet's freedom, when he was confined as insane by the Duke Alfonso d'Este.—Vincenzo was much esteemed for his piety, justice, and liberality. He was successively followed by his three sons, Francesco, Ferdinando, and Vincentio, who died without heirs, and thus the direct line of the ducal branch became extinct. A collateral branch, in the person of Charles I., Duke of Nevers, son of Ludovico, the brother of Guglielmo the humpbacked, claimed the duchy, which was contested by his cousin Cesar, Duke of Guastalla. This family feud led to a general war, in which France supported Nevers, and the empire claimed the right of adjudging Mantua, as an imperial fief, to a candidate of imperial election. Mantua in 1629 was stormed, sacked, and stripped of all its magnificent possessions, by the imperialists, and never regained its former splendour. Charles de Nevers submitted finally to the emperor, and was installed in the duchy. The artistic treasures collected for ages by the G. princes were scattered throughout Europe, and came into the possession of several of the reigning sovereigns. The successors of Charles were dissipated and silly, and the tenth and last Duke of Mantua, Ferdinand-Charles, was the most contemptible and dissolute of all. As he

838

had countenanced the French in the War of the Succession, the Emperor Joseph I. deprived him of his states, placing him under the ban of the empire. He died in exile in 1708, leaving no issue.

GONZALVO DI CORDOVA (G. Hernandez y Aguilar), a celebrated Spanish warrior, was born at Montillo, near Cordova, in 1453. He served with great distinction first in the war with the Moors of Granada, and afterwards in the Portuguese campaign. At the close of the final contest with Granada, he concluded the negotiation with Boabdil (Abu Abdallah), king of the Moors, in such a masterly manner, that the rulers of Spain bestowed upon him a pension and a large estate in the conquered territory. He was next sent to the assistance of Ferdinand, king of Naples, against the French. In less than a year, G., with his limited resources, had conquered the greater part of the kingdom, and obtained the appellation of 'El Gran Capitano.' In conjunction with King Ferdinand, he succeeded in completely expelling the French from Italy; and in August 1498 returned to Spain, having received in return for his valuable services an estate in the Abruzzi, with the title of Duke of San Angelo. When the partition of the kingdom of Naples was determined upon by a compact entered into at Granada, 11th November 1500, G. again set out for Italy, with a body of 4300 men, and on the way took Zante and Cephalonia from the Turks, and restored them to the Venetians. He then landed in Sicily, occupied Naples and Calabria, and demanded from the French that, in compliance with the compact, they should yield up Capitanata and Basilicata. This demand being rejected, a war broke out between the two belligerent powers, which was waged with varied success. After the victory of Cerignola, in April 1503, G. took possession of Calabria, Abruzzo, Apulia, even the city of Naples itself, and then laid siege to Gaëta, but was forced to retreat before a superior force of the enemy. On the 29th December of the same year, however, he fell upon them unexpectedly near the Garigliano, and obtained a complete victory, 29th December 1503. The French army was almost annihilated; the fortress of Gaëta fell; and the possession of Naples was secured to the Spaniards. King Ferdinand bestowed the duchy of Sees upon the conqueror, and appointed him viceroy of Naples, with unlimited authority. His good-fortune, however, made him many powerful enemies; and G. was recalled to Spain, where the king treated him with marked neglect. G. now betook himself to his estates in Granada; but after the defeat of the new viceroy in Naples by Gaston de Foix, he was again appointed to the command of the Spanish-Italian army. Mental suffering, however, had undermined the old hero's health, and on the 2d December 1515 he died at Granada.
